

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

78M6612

Single-Phase, Dual-Outlet

Power and Energy Measurement IC

DATA SHEET

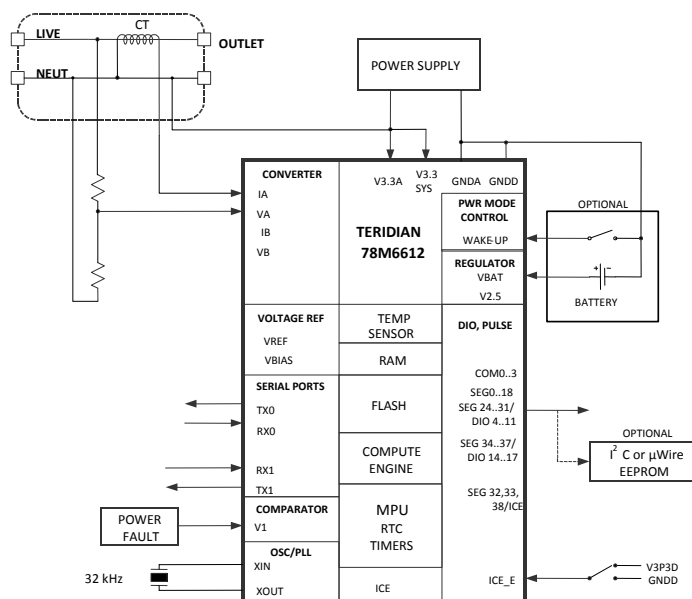

DS_6612_001

DESCRIPTION

The Teridian™ 78M6612 is a highly integrated, single-phase, power and energy measurement and monitoring system-on-chip (SoC) that includes a 32-bit compute engine (CE), an MPU core, RTC, and flash. Our Single Converter Technology® with a 22-bit delta-sigma ADC, four analog inputs, digital temperature compensation, and precision voltage reference supports a wide range of single-phase, dual-outlet power measurement applications with very few external components.

With measurement technology leveraged from Maxim's flagship utility metering ICs, the device offers features including 32 KB of flash program memory, 2 KB shared RAM, three low-power modes with internal timer or external event wake-up, two UARTs, I²C/MICROWIRE® EEPROM I/F, and an in-system programmable flash. Complete outlet measurement unit (OMU) and AC power monitor (AC-PMON) firmware is available or can be preloaded into the IC.

A complete array of ICE and development tools, programming libraries and reference designs enable rapid development and certification of power and energy measurement solutions that meet the most demanding worldwide electricity metering standards.

Teridian is a trademark and Single Converter Technology is a registered trademark of Maxim Integrated Products, Inc.
MICROWIRE is a registered trademark of National Semiconductor Corp.

FEATURES

- Measures Each Outlet of a Duplex Receptacle with a Single IC
- Provides Complete Energy Measurement and Communication Protocol Capability in a Single IC
- Intelligent Switch Control Capability
- < 0.5% Wh Accuracy Over 2000:1 Current Range and Over Temperature
- Exceeds IEC 62053/ANSIC12.20 Standards
- Voltage Reference < 40 ppm/°C
- Four Sensor Inputs – VDD Referenced
- Low Jitter Wh and VARh Pulse Test Outputs (10 kHz max)
- Pulse Count for Pulse Outputs
- Line Frequency Count for RTC
- Digital Temperature Compensation
- Sag Detection for Phase A and B
- Independent 32-Bit Compute Engine
- 46-64 Hz Line Frequency Range with Same Calibration
- Phase Compensation ($\pm 7^\circ$)
- Battery Backup for RTC and Battery Monitor
- Three Battery Modes with Wake-Up Timer:
 - Brownout Mode (48 μ A)
 - LCD Mode (5.7 μ A)
 - Sleep Mode (2.9 μ A)
- Energy Display on Main Power Failure
- Wake-Up Timer
- 22-Bit Delta-Sigma ADC
- 8-Bit MPU (80515), 1 Clock Cycle per Instruction with Integrated ICE for MPU Debug
- RTC with Temperature Compensation
- Auto-Calibration
- Hardware watchdog Timer, Power-Fail Monitor
- LCD Driver (Up to 152 Pixels)
- Up to 18 General-Purpose I/O Pins
- 32 kHz Time Base
- 32 KB Flash with Security
- 2 KB MPU XRAM
- Two UARTs
- Digital I/O Pins Compatible with 5 V Inputs
- 64-Pin LQFP or 68-Pin QFN Package
- RoHS-Compliant (6/6) Lead(Pb)-Free Packages
- Complete Application Firmware Available

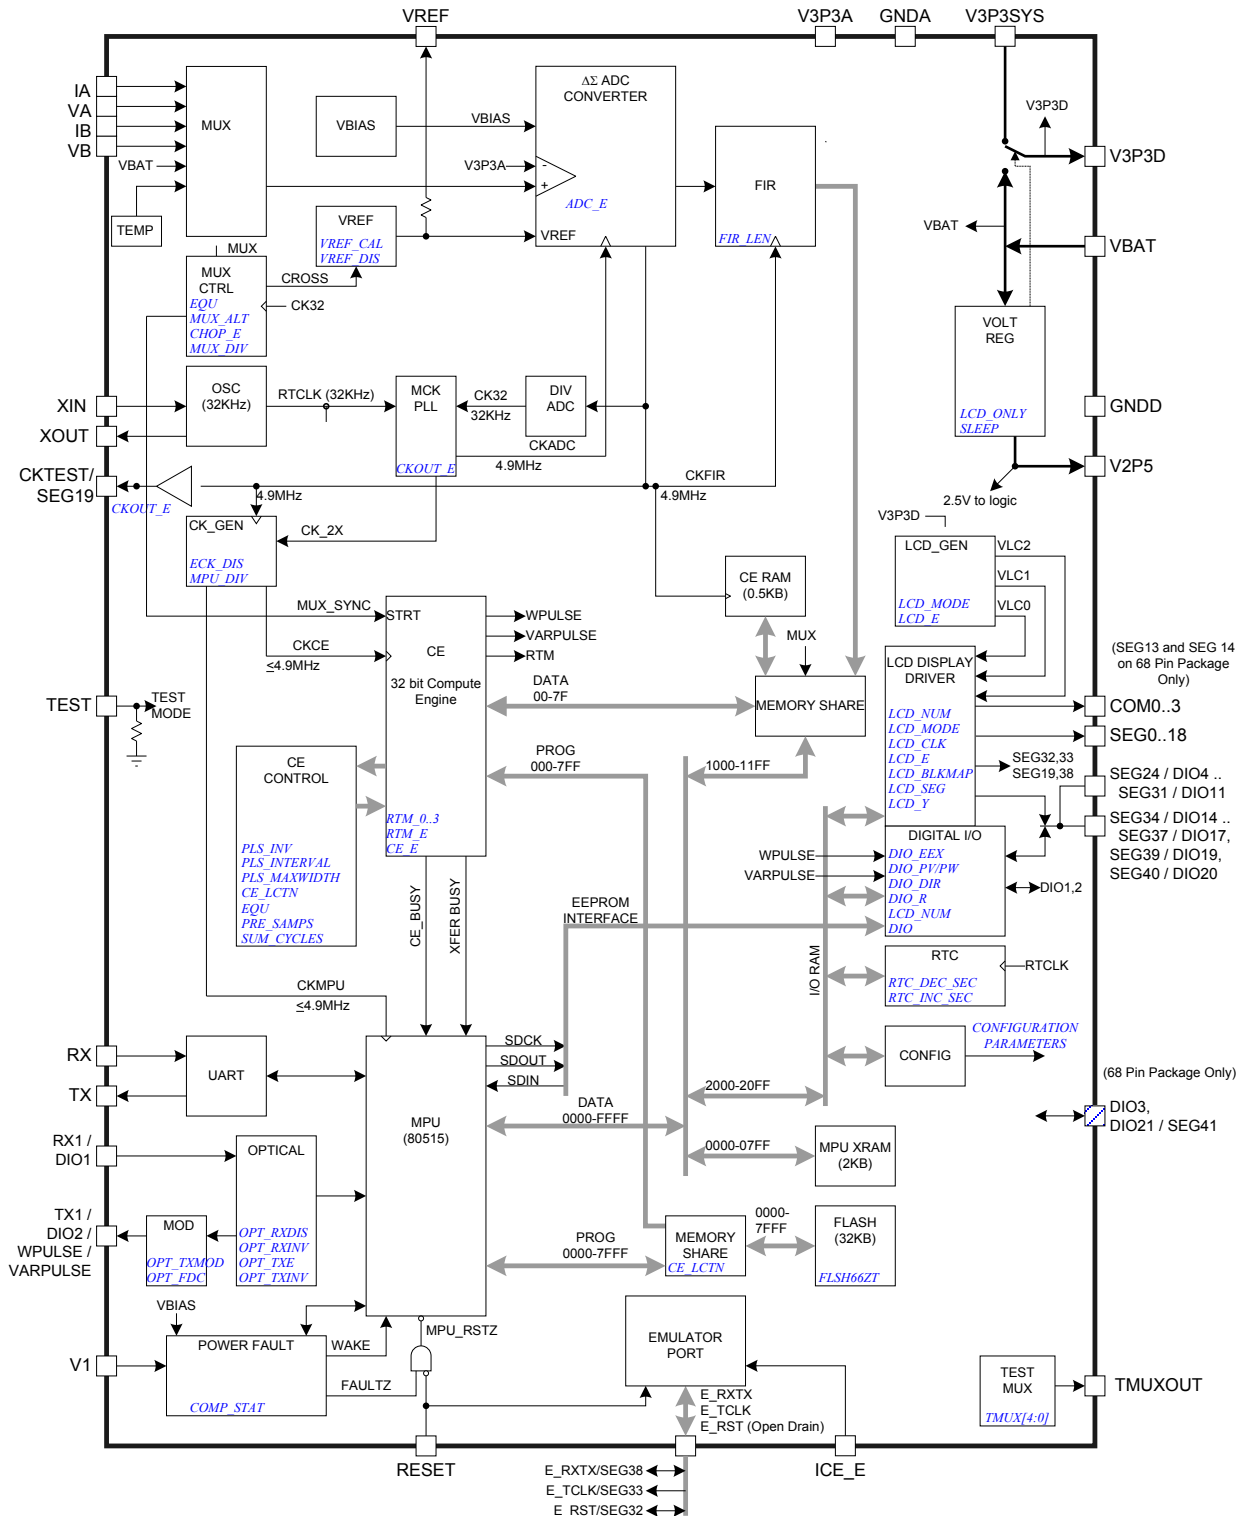

Figure 1: IC Functional Block Diagram

1 Hardware Description

1.1 Hardware Overview

The Teridian 78M6612 single-chip measurement and monitoring IC integrates all the primary AC measurement and control blocks required to implement a solid-state electricity Power and Energy Measurement function. The 78M6618 includes:

- A four-input analog front end (AFE)
- An independent digital computation engine (CE)
- An 8051-compatible microprocessor (MPU) which executes one instruction per clock cycle (80515)
- A precision voltage reference
- A temperature sensor
- LCD drivers
- RAM and Flash memory
- A real time clock (RTC)
- A variety of I/O pins

Various current sensor technologies are supported including Current Transformers (CT), and Resistive Shunts.

In a typical application, the 32-bit compute engine (CE) of the 78M6612 sequentially processes the samples from the analog inputs on pins IA, VA, IB, VB and performs calculations to measure active energy (Wh), reactive energy (VARh), A^2h , and V^2h for four-quadrant measurement. These measurements are then accessed by the MPU, processed further, and output using the peripheral devices available to the MPU.

In addition to advanced measurement functions, the real time clock function allows the 78M6612 to record time of use (TOU) measurement information for multi-rate applications and to time-stamp events. Measurements can be displayed on 3.3 V LCDs if desired. Flexible mapping of LCD display segments will facilitate utilization of existing custom LCDs. Design trade-off between number of LCD segments vs. DIO pins can be implemented in software to accommodate various requirements.

In addition to the temperature-trimmed ultra-precision voltage reference, the on-chip digital temperature compensation mechanism includes a temperature sensor and associated controls for correction of unwanted temperature effects on measurement and RTC accuracy, e.g. to meet the requirements of ANSI and IEC standards. Temperature-dependent external components such as crystal oscillator, current transformers (CTs), and their corresponding signal conditioning circuits can be characterized and their correction factors can be programmed to produce measurements with exceptional accuracy over the industrial temperature range.

A block diagram of the IC is shown in [Figure 1](#). A detailed description of various functional blocks follows.

1.2 Analog Front End (AFE)

The AFE functions as a data acquisition system, controlled by the MPU. It consists of an input multiplexer, a delta-sigma A/D converter, and a voltage reference. The main signals (IA, VA, IB, VB) are sampled and the ADC counts obtained are stored in CE DRAM where they can be accessed by the CE and, if necessary, by the MPU.

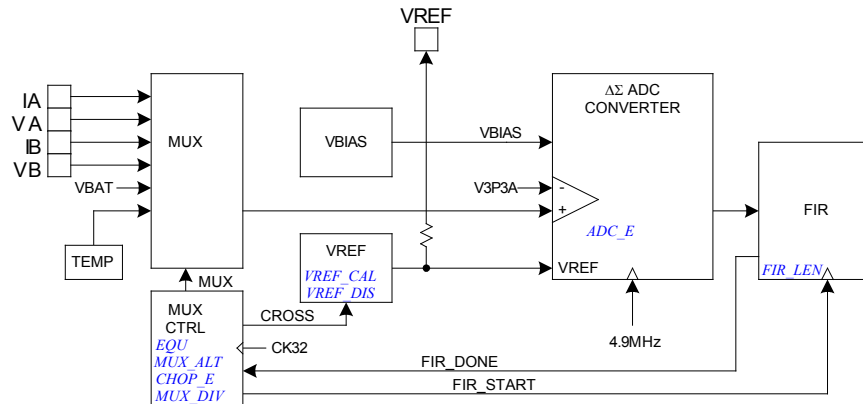

Figure 2: AFE Block Diagram

1.2.1 Input Multiplexer

The input multiplexer supports up to four input signals that are applied to pins IA, VA, IB, and VB of the device. Additionally, using the alternate multiplexer selection, it has the ability to select temperature and the battery voltage. The multiplexer can be operated in two modes:

- During a normal multiplexer cycle, the signals from the IA, IB, VA, and VB pins are selected.
- During the alternate multiplexer cycle, the temperature signal (TEMP) and the battery monitor are selected, along with the signal sources shown in [Table 1](#). To prevent unnecessary drainage on the battery, the battery monitor is enabled only with the *BME* bit (0x2020[6]) in the I/O RAM.

The alternate multiplexer cycles are usually performed infrequently (e.g. every second or so) by the MPU. In order to prevent disruption of the voltage tracking PLL and voltage allpass networks, VA is not replaced in the ALT mux selections. [Table 1](#) details the regular and alternative multiplexer sequences. Missing samples due to an ALT multiplexer sequence are filled in by the CE.

Table 1: Inputs Selected in Regular and Alternate Multiplexer Cycles

	Regular MUX Sequence				ALT MUX Sequence			
	Mux State				Mux State			
<i>EQU</i>	0	1	2	3	0	1	2	3
2	IA	VA	IB	VB	TEMP	VA	VBAT	VB

In a typical application, IA and IB are connected to current sensors that sense the current on each branch of the line voltage. VA and VB are typically connected to voltage sensors through resistor dividers. The multiplexer control circuit is clocked by CK32, the 32.768 kHz clock from the PLL block, and launches with each new pass of the CE program. The duration of each multiplexer state depends on the number of ADC samples processed by the FIR.

1.2.2 A/D Converter (ADC)

A single delta-sigma A/D converter digitizes the voltage and current inputs to the 78M6612. The resolution of the ADC is configurable to either 21 or 22 bit. At the end of each ADC conversion, the FIR filter output data is stored into the CE RAM location.

1.2.3 FIR Filter

The finite impulse response filter is an integral part of the ADC and it is optimized for use with the multiplexer. The purpose of the FIR filter is to decimate the ADC output to the desired resolution. At the end of each ADC conversion, the output data is stored into the CE RAM location determined by the multiplexer selection. FIR data is stored LSB justified, but shifted left by nine bits.

1.2.4 Voltage References

The device includes an on-chip precision bandgap voltage reference that incorporates auto-zero techniques. The reference is trimmed to minimize errors caused by component mismatch and drift. The result is a voltage output with a predictable temperature coefficient.

1.2.5 Temperature Sensor

The 78M6612 includes an on-chip temperature sensor implemented as a bandgap reference. It is used to determine the die temperature. The MPU reads the temperature sensor output during alternate multiplexer cycles. The primary use of the temperature data is to determine the magnitude of compensation required to offset the thermal drift in the system (see [Section 3.4 Temperature Compensation](#)).

1.2.6 Battery Monitor

The 78M6618 also has the ability to measure battery voltage by the ADC during alternative multiplexer frames. When set, an on-chip 45 k Ω load resistor is applied to the battery and a scaled fraction of the battery voltage is applied to the ADC input. Battery operating modes are not supported in all firmware libraries. Contact Maxim support for more information.

1.3 Digital Computation Engine (CE)

The CE, a dedicated 32-bit signal processor, performs the precision computations necessary to accurately measure energy. The CE calculations and processes include:

- Multiplication of each current sample with its associated voltage sample to obtain the energy per sample (when multiplied with the constant sample time).
- Frequency-insensitive delay cancellation on all four channels (to compensate for the delay between samples caused by the multiplexing scheme).
- 90° phase shifter (for narrowband VAR calculations).
- Pulse generation.
- Monitoring of the input signal frequency (for frequency and phase information).
- Monitoring of the input signal amplitude (for sag detection).
- Scaling of the processed samples based on calibration coefficients.

CE code is provided by Maxim as a part of the application firmware available. The CE is not programmable by the user. Measurement algorithms in the CE code can be customized by Maxim upon request.

The CE program resides in Flash memory. Allocated Flash space for the CE program cannot exceed 1024 words (2 KB). The CE can access up to 2 KB of data RAM (XRAM), or 512 32-bit data words. The CE is also aided by support hardware to facilitate implementation of equations, pulse counters and accumulators. Usage of this hardware is firmware specific.

1.3.1 Real-Time Monitor

The CE contains a Real-Time Monitor (RTM), which can be programmed to monitor four selectable CE DRAM locations at full sample rate for system debug purposes. The four monitored locations can be serially output to the TMUXOUT pin via the digital output multiplexer at the beginning of each CE code pass. The RTM output is clocked by CKTEST.

1.3.2 Pulse Generator

The CE provides four pulse generators used to output CE status indicators (e.g. SAG) directly to designated DIO pins.

1.3.3 Data RAM (XRAM)

The CE and MPU use a single general-purpose Data RAM (also referred to as XRAM). When the MPU and CE are clocking at maximum frequency (10 MHz), the RAM may be accessed up to four times during each 100 ns interval. These consist of two MPU accesses, one CE access and one SPI access.

1.4 80515 MPU Core

The 78M6612 includes an 80515 MPU (8-bit, 8051-compatible) that processes most instructions in one clock cycle. Using a 5 MHz (4.9152 MHz) clock results in a processing throughput of 5 MIPS. The 80515 architecture eliminates redundant bus states and implements parallel execution of fetch and execution phases. Normally a machine cycle is aligned with a memory fetch, therefore, most of the 1-byte instructions are performed in a single machine cycle (MPU clock cycle). This leads to an 8x average performance improvement (in terms of MIPS) over the Intel® 8051 device running at the same clock frequency. Actual processor clocking speed can be adjusted to the total processing demand of the application (measurement calculations, memory management and I/O management).

- ✓ Typical power and energy measurement functions based on the results provided by the internal 32-bit compute engine (CE) are available for the MPU as part of Maxim's standard library. A standard ANSI "C" 80515 application program library is available to help reduce design cycle.

1.4.1 UARTs

The 78M6612 includes two UARTs (UART0 and UART1) that can be programmed to communicate with a variety of external devices. The UARTs are dedicated 2-wire serial interfaces, which can communicate at rates up to 38,400 bits/s. All UART transfers are programmable for parity enable, parity, 2 stop bits/1 stop bit and XON/XOFF option for variable communication baud rates from 300 to 38,400 bps.

1.5 On-Chip Resources

1.5.1 Oscillator

The 78M6612 oscillator drives a standard 32.768 kHz watch crystal. These crystals are accurate and do not require a high-current oscillator circuit. The 78M6612 oscillator has been designed specifically to handle these crystals and is compatible with their high impedance and limited power handling capability.

1.5.2 PLL and Internal Clocks

Timing for the device is derived from the 32.768 kHz oscillator output. On-chip timing functions include:

- The MPU master clock
- A real time clock (RTC)
- The delta-sigma sample clock.

The two general-purpose counter/timers are contained in the MPU.

The ADC master clock, CKADC, is generated by an on-chip PLL. It multiplies the oscillator output frequency (CK32) by 150.

The CE clock frequency is always $CK32 * 150$, or 4.9152 MHz, where CK32 is the 32 kHz clock. The MPU clock frequency is determined by MPU_DIV and can be $4.9152 \text{ MHz} * 2^{-MPU_DIV}$ Hz where MPU_DIV varies from 0 to 7 (MPU_DIV is 0 on power-up). This makes the MPU clock scalable from 4.9152 MHz down to 38.4 kHz. The circuit also generates a 2x MPU clock for use by the emulator. This 2x MPU clock is not generated when ECK_DIS is asserted by the MPU.

The setting of MPU_DIV is maintained when the device transitions to BROWNOUT mode, but the time base in BROWNOUT mode is 28,672 Hz.

1.5.3 Real-Time Clock (RTC)

The RTC is driven directly by the crystal oscillator. The RTC consists of a counter chain and output registers. The counter chain consists of seconds, minutes, hours, day of week, day of month, month, and year. The RTC is not supported in all firmware libraries. Contact Maxim support for more information.

1.5.4 Temperature Sensor

The device includes an on-chip temperature sensor for determining the temperature of the bandgap reference. The MPU may request an alternate multiplexer frame containing the temperature sensor output by asserting *MUX_ALT*. The primary use of the temperature data is to determine the magnitude of compensation required to offset the thermal drift in the system (see [Section 3.4 Temperature Compensation](#)).

1.5.5 Flash Memory

The 78M6612 includes 32 KB of on-chip Flash memory. The Flash memory primarily contains MPU and CE program code. It also contains images of the CE DRAM, MPU RAM, and I/O RAM. On power-up, before enabling the CE, the MPU copies these images to their respective locations.

The Flash memory is segmented into individually erasable 1024-byte pages. Flash space allocated for the CE program is limited to 1024 words (2 KB). The CE program must begin on a 1-KB boundary of the Flash address space.

Flash Write Procedures

The MPU has the ability to write to the Flash memory when the CE is disabled. As an alternative to using Flash, a small EEPROM can store data without compromises. EEPROM interfaces are included in the device.

Updating Individual Bytes in Flash Memory

The original state of a Flash byte is 0xFF (all ones). Once a value other than 0xFF is written to a Flash memory cell, overwriting with a different value usually requires that the cell be erased first. Since cells cannot be erased individually, the page has to be copied to RAM, followed by a page erase. After this, the page can be updated in RAM and then written back to the Flash memory.

Flash Erase Procedures

Flash erasure is initiated by writing a specific data pattern to specific SFR registers in the proper sequence. These special pattern/sequence requirements prevent inadvertent erasure of the Flash memory.

The mass erase sequence is:

1. Write 1 to the *FLSH_MEEN* bit (SFR address 0xB2[1]).
2. Write pattern 0xAA to *FLSH_ERASE* (SFR address 0x94).

The mass erase cycle can only be initiated when the ICE port is enabled.

The page erase sequence is:

1. Write the page address to *FLSH_PGADR* (SFR address 0xB7[7:1]).
2. Write pattern 0x55 to *FLSH_ERASE* (SFR address 0x94).

1.5.6 Optical Interface

The device includes an interface to implement an IR/optical port on UART1. The pin TX1 is designed to directly drive an external LED for transmitting data on an optical link. The pin RX1 is designed to sense the input from an external photo detector used as the receiver for the optical link. The IR/optical interface is not supported in all firmware libraries. Contact Maxim support for more information.

1.5.7 Digital I/O

The device includes up to 18 pins (QFN 68 package) or 16 pins (LQFP 64 package) of general purpose digital I/O. These pins are compatible with 5V inputs (no current-limiting resistors are needed). Some of them are dedicated DIO (DIO3), some are dual-function that can alternatively be used as LCD drivers (DIO4-11, 14-17, 19-21) and some share functions with the optical port (DIO1, DIO2). On reset or power-up, all DIO pins are inputs until they are configured for the desired direction under MPU control. The pins are configured by the DIO registers and by the five bits of the *LCD_NUM* register (located in I/O RAM). Once declared as DIO, each pin can be configured independently as an input or output with the *DIO_DIRn* bits. A 3-bit configuration word, *DIO_Rx*, can be used for certain pins, when configured as DIO, to individually assign an internal resource such as an interrupt or a timer control. [Table 2](#) lists the direction registers and configurability associated with each group of DIO pins. [Table 3](#) shows the configuration for a DIO pin through its associated bit in its *DIO_DIR* register.

Tables showing the relationship between *LCD_NUM* and the available segment/DIO pins can be found in [Section 3.5 Connecting LCDs](#) and in [Section 4.3 I/O Description](#) under *LCD_NUM[4:0]*.

Table 2: Data/Direction Registers and Internal Resources for DIO Pin Groups

DIO	x	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

	<i>DIO_DIR2</i> (SFR 0xA1)							
Internal Resources Configurable	N	N	–	N	N	N	–	–

Table 3: DIO_DIR Control Bit

DIO Pin n Function	DIO_DIR [n]	
	0	1
	Input	Output

Additionally, if DIO6 and DIO7 are declared outputs, they can be configured as dedicated pulse outputs (WPULSE = DIO6, VARPULSE = DIO7) using *DIO_PW* and *DIO_PV* registers. In this case, DIO6 and DIO7 are under CE control. DIO4 and DIO5 can be configured to implement the EEPROM Interface.

If the optical UART is not used, TX1 and RX1 can be configured as dedicated DIO pins (DIO1, DIO2, see [Section 1.5.6 Optical Interface](#)).

A 3-bit configuration word, I/O RAM register, *DIO_Rx* (0x2009[2:0] through 0x200E[6:4]) can be used for certain pins, when configured as DIO, to individually assign an internal resource such as an interrupt or a timer control (see [Table 2](#) for DIO pins available for this option). This way, DIO pins can be tracked even if they are configured as outputs.

Tracking DIO pins configured as outputs is useful for pulse counting without external hardware.

When driving LEDs, relay coils etc., the DIO pins should sink the current into ground (as shown in [Figure 3, right](#)), not source it from V3P3D (as shown in [Figure 3, left](#)). This is due to the resistance of the internal switch that connects V3P3D to either V3P3SYS or VBAT.

When configured as inputs, the dual-function (DIO/SEG) pins should not be pulled above V3P3SYS in MISSION and above VBAT in LCD and BROWNOUT modes. Doing so will distort the LCD waveforms of the other pins. This limitation applies to any pin that can be configured as a LCD driver.

The control resources selectable for the DIO pins are listed in [Table 4](#). If more than one input is connected to the same resource, the resources are combined using a logical OR.

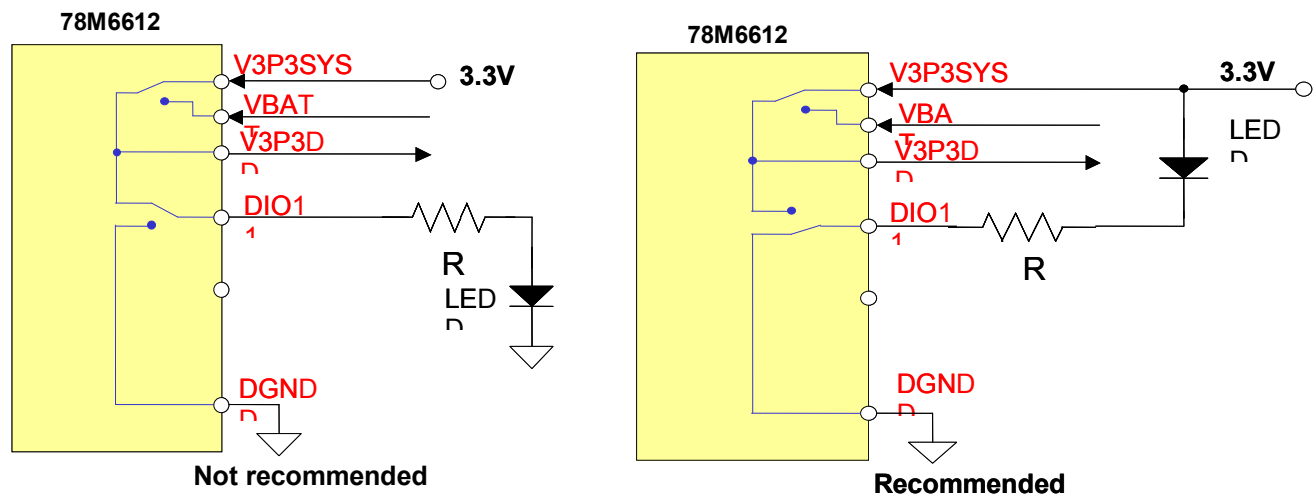

**Figure 3: Connecting an External Load to DIO Pins**

Table 4: Selectable Controls using the *DIO_DIR* Bits

<i>DIO_R</i> Value	Resource Selected for DIO Pin
0	NONE
1	Reserved
2	T0 (counter0 clock)
3	T1 (counter1 clock)
4	High priority I/O interrupt (INT0 rising)
5	Low priority I/O interrupt (INT1 rising)
6	High priority I/O interrupt (INT0 falling)
7	Low priority I/O interrupt (INT1 falling)

1.5.8 LCD Drivers

The device in the 68-pin QFN package contains 20 dedicated LCD segment drivers in addition to the 18 multi-use pins described above. Thus, the device is capable of driving between 80 to 152 pixels of LCD display with 25% duty cycle (or 60 to 114 pixels with 33% duty cycle). At eight pixels per digit, this corresponds to 10 to 19 digits.

The device in the 64-pin LQFP package contains 18 dedicated LCD segment drivers in addition to the 17 multi-use pins described above. Thus, the device is capable of driving between 72 to 140 pixels of LCD display with 25% duty cycle (or 60 to 105 pixels with 33% duty cycle). At eight pixels per digit, this corresponds to 9 to 17 digits.

The LCD drivers are grouped into four commons and up to 38 segment drivers (68-pin package), or 4 commons and 35 segment drivers (64-pin package). The LCD interface is flexible and can drive either digit segments or enunciator symbols.

Segment drivers SEG18 and SEG19 can be configured to blink at either 0.5 Hz or 1 Hz. The blink rate is controlled by *LCD_Y*. There can be up to four pixels/segments connected to each of these drivers. *LCD_BLKMAP18[3:0]* and *LCD_BLKMAP19[3:0]* identify which pixels, if any, are to blink.

LCD interface memory is powered by the non-volatile supply. The bits of the LCD memory are preserved in LCD and SLEEP modes, even if their pin is not configured as SEG. In this case, they can be useful as general-purpose non-volatile storage.

1.5.9 EEPROM Interface

The 78M6612 provides hardware support for an optional two-pin or a three-wire (μ -wire) EEPROM interface.

Two-Pin EEPROM Interface

The dedicated 2-pin serial interface communicates with external EEPROM devices. The interface is multiplexed onto the DIO4 (SCK) and DIO5 (SDA) pins.

Three-Wire (μ -Wire) EEPROM Interface

A 500 kHz 3-wire interface, using SDATA, SCK, and a DIO pin for CS is also available.

1.5.10 Hardware Watchdog Timer

In addition to the basic watchdog timer included in the 80515 MPU, an independent, robust, fixed-duration, watchdog timer (WDT) is included in the device. It uses the crystal oscillator as its time base and must be refreshed by the MPU firmware at least every 1.5 seconds. When not refreshed on time the WDT overflows, and the part is reset as if the RESET pin were pulled high, except that the I/O RAM bits will be maintained. 4096 oscillator cycles (or 125 ms) after the WDT overflow, the MPU will be launched from program address 0x0000. Asserting ICR_E will deactivate the WDT.

The WDT can also be disabled by tying the V1 pin to V3P3. Of course, this also deactivates V1 power fault detection. Since there is no method in firmware to disable the crystal oscillator or the WDT, it is guaranteed that whatever state the part might find itself in, upon WDT overflow, the part will be reset to a known state.

Figure 4: Functions Defined by V1

1.5.11 Test Ports (TXUXOUT pin)

One out of 16 digital or 8 analog signals can be selected to be output on the TMUXOUT pin. The function of the multiplexer is described in the applicable firmware documentation.

2 Functional Description

2.1 Theory of Operation

The energy delivered by a power source into a load can be expressed as:

$$E = \int_0^t V(t)I(t)dt$$

The following formulas apply for wide band mode (true RMS):

- $P = \sum (i(t) * v(t))$
- $Q = \sqrt{S^2 - P^2}$
- $S = V * I$
- $V = \sqrt{\sum v(t)^2}$
- $I = \sqrt{\sum i(t)^2}$

For actual measurement equations, refer to the applicable *78M6612 Firmware Description Document*.

For some applications, not only voltage and current amplitudes, but also phase angles and harmonic content may change constantly. Thus, simple RMS measurements are inherently inaccurate. A modern solid-state electricity measurement IC such as the 78M6612 functions by emulating the integral operation above, i.e. it processes current and voltage samples through an ADC at a constant frequency. As long as the ADC resolution is high enough and the sample frequency is beyond the harmonic range of interest, the current and voltage samples, multiplied with the time period of sampling will yield an accurate quantity for the momentary energy. Summing up the momentary energy quantities over time will result in accumulated energy.

Figure 5: Voltage, Current, Momentary and Accumulated Energy

Figure 5 shows the shapes of $V(t)$, $I(t)$, the momentary power and the accumulated power, resulting from 50 samples of the voltage and current signals over a period of 20 ms. The application of 240 VAC and 100 A results in an accumulation of 480 Ws (= 0.133 Wh) over the 20 ms period, as indicated by the Accumulated Power curve. The described sampling method works reliably, even in the presence of dynamic phase shift and harmonic distortion.

2.2 Fault and Reset Behavior

2.2.1 Reset Mode

When the RESET pin is pulled high, all digital activity stops. The oscillator and RTC module continue to run. Additionally, all I/O RAM bits are set to their default states. As long as V1, the input voltage at the power fault block, is greater than VBIAS, the internal 2.5 V regulator continues to provide power to the digital section.

Once initiated, the reset mode persists until the reset timer times out. This occurs in 4096 cycles of the real time clock after RESET goes low, at which time the MPU begins executing its preboot and boot sequences from address 00.

2.2.2 Power Fault Circuit

The 78M6612 includes a comparator to monitor system power fault conditions. When the output of the comparator falls ($V1 < VBIAS$), the PLL status bits in the I/O RAM are zeroed and the IC power downs. Once system power returns, the MPU remains in reset and does not start until 2048 to 4096 CK32 clock cycles later. Program execution starts at address 0x00. MPU RAM will be re-initialized.

2.3 Data Flow

The data flow between the Compute Engine (CE) and the MPU is shown in [Figure 6](#). In a typical application, the 32-bit CE sequentially processes the samples from the current and voltage inputs on pins IA, VA, IB, and VB, performing calculations to measure active power (Wh), reactive power (VARh), A^2h , and V^2h for four-quadrant measurement. These measurements are then accessed by the MPU, processed further and output using the peripheral devices available to the MPU.

Figure 6: MPU/CE Data Flow

2.4 CE/MPU Communication

Figure 7 shows the functional relationship between the CE and the MPU. The CE is controlled by the MPU via shared registers in the I/O RAM and RAM. The CE outputs two interrupt signals to the MPU to indicate the CE is actively processing data and the CE is updating data to the output region of the RAM.

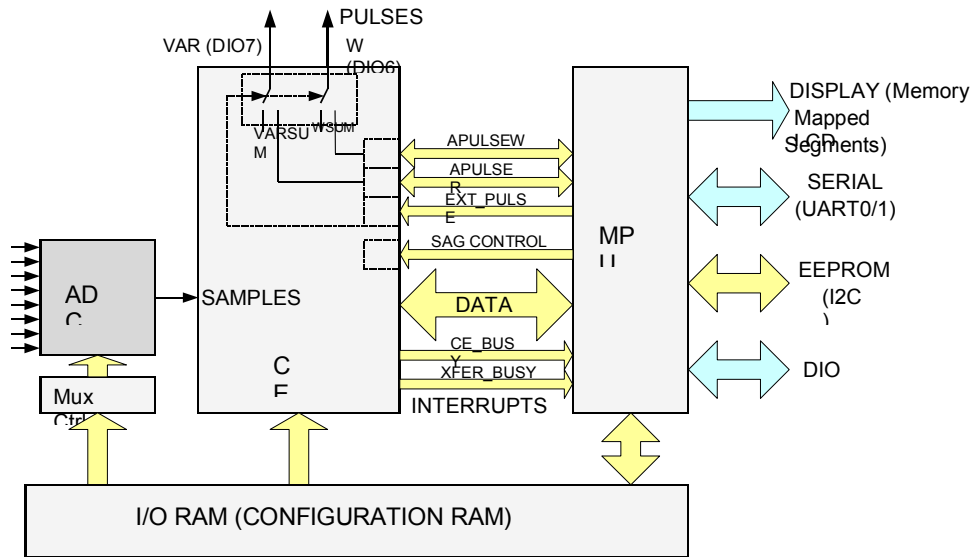

Figure 7: MPU/CE Communication

3 Application Information

3.1 Connection of Sensors (CT, Resistive Shunt)

Figure 8, Figure 9, and Figure 10 show how resistive voltage dividers, resistive current shunts, and current transformers are connected to the voltage and current inputs of the 78M6612.

$$V_{out} = V_{in} * R_{out} / (R_{out} + R_{in})$$

Figure 8: Resistive Voltage Divider

$$V_{out} = R * I_{in}$$

Figure 9: Resistive Current Shunt

$$V_{out} = R * I_{out} = R * I_{in} / N$$

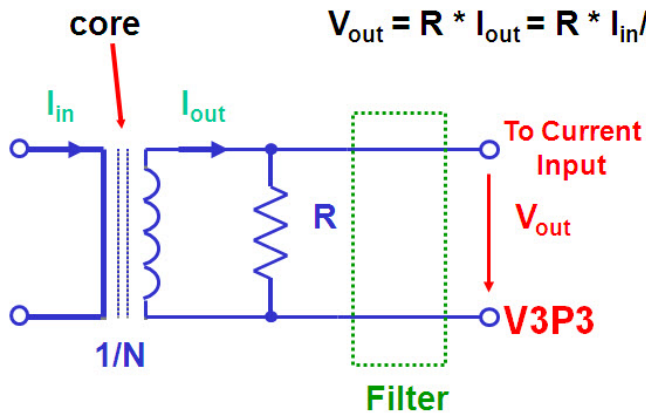

Figure 10: Current Transformer

3.2 Connecting 5 V Devices

All digital input pins of the 78M6612 are compatible with external 5 V devices. I/O pins configured as inputs do not require current-limiting resistors when they are connected to external 5 V devices.

3.3 Temperature Measurement

Measurement of absolute temperature uses the on-chip temperature sensor and applying the following formula:

$$T = \frac{(N(T) - N_n)}{S_n} + T_n$$

In the above formula, T is the temperature in °C, $N(T)$ is the ADC count at temperature T , N_n is the ADC count at 25°C, S_n is the sensitivity in LSB/°C and T_n is +25 °C.

3.4 Temperature Compensation

Temperature Coefficients: The internal voltage reference is calibrated during device manufacture.

The temperature coefficients TC1 and TC2 are given as constants that represent typical component behavior (in $\mu\text{V}/^\circ\text{C}$ and $\mu\text{V}/^\circ\text{C}^2$, respectively).

Since TC1 and TC2 are given in $\mu\text{V}/^\circ\text{C}$ and $\mu\text{V}/^\circ\text{C}^2$, respectively, the value of the VREF voltage (1.195V) has to be taken into account when transitioning to PPM/°C and PPM/°C². This means that PPMC = 26.84*TC1/1.195, and PPMC2 = 1374*TC2/1.195).

Temperature Compensation: The CE provides the bandgap temperature to the MPU, which then may digitally compensate the power outputs for the temperature dependence of VREF.

The MPU, not the CE, is entirely in charge of providing temperature compensation. The MPU applies the following formula to determine $GAIN_ADJ$ (address 0x12). In this formula $TEMP_X$ is the deviation from nominal or calibration temperature expressed in multiples of 0.1°C:

$$GAIN_ADJ = 16385 + \frac{TEMP_X \cdot PPMC}{2^{14}} + \frac{TEMP_X^2 \cdot PPMC2}{2^{23}}$$

In a power and energy measurement unit, the 78M6612 is not the only component contributing to temperature dependency. A whole range of components (e.g. current transformers, resistor dividers, power sources, filter capacitors) will contribute temperature effects. Since the output of the on-chip temperature sensor is accessible to the MPU, temperature-compensation mechanisms with great flexibility are possible (e.g. system-wide temperature correction over the entire unit rather than local to the chip).

3.5 Connecting LCDs

The 78M6612 has an on-chip LCD controller capable of controlling static or multiplexed LCDs. [Figure 11](#) shows the basic connection for an LCD.

Figure 11: Connecting LCDs

The LCD segment pins can be organized in the following groups:

- Seventeen pins are dedicated LCD segment pins (SEG0 to SEG13, SEG16 to SEG18).
- Four pins are dual-function pins CKTEST/SEG19, E_RXTX/SEG38, E_TCLK/SEG33, and E_RST/SEG32.
- Fourteen pins are available as combined DIO and segment pins SEG24/DIO4 to SEG31/DIO11, SEG34/DIO14 to SEG37/DIO17, SEG39/DIO19, and SEG40/DIO20.
- The QFN-68 package adds an additional combination pin, SEG41/DIO21. Also adds two additional LCD segment pins, SEG13 and SEG14.

3.6 Connecting I²C EEPROMs

I²C EEPROMs or other I²C compatible devices should be connected to the DIO pins DIO4 and DIO5, as shown in [Figure 12](#).

Pull-up resistors of roughly 10 k Ω to V3P3D should be used for both SCL and SDA signals. The *DIO_EEX* register in I/O RAM must be set to 01 in order to convert the DIO pins DIO4 and DIO5 to I²C pins SCL and SDA.

Figure 12: I²C EEPROM Connection

3.7 Connecting Three-Wire EEPROMs

μ Wire EEPROMs and other compatible devices should be connected to the DIO pins DIO4 and DIO5, as shown in Figure 13 and described below:

- DIO5 connects to both the DI and DO pins of the three-wire device.
- The CS pin must be connected to a vacant DIO pin of the 78M6618.
- In order to prevent bus contention, a 10 k Ω resistor is used to separate the DI and DO signals.
- The CS and CLK pins should be pulled down with resistors to prevent operation of the three-wire device on power-up, before the 78M6618 can establish a stable signal for CS and CLK.
- The *DIO_EEX* register in I/O RAM must be set to 2 (b10) in order to convert the DIO pins DIO4 and DIO5 to μ Wire pins.

The μ -Wire EEPROM interface is only functional when $MPU_DIV[2:0] = 000$.

Figure 13: Three-Wire EEPROM Connection

3.8 UART0 (TX0/RX0)

The UART0 RX0 pin should be pulled down by a 10 k Ω resistor and additionally protected by a 100 pF ceramic capacitor, as shown in Figure 14.

Figure 14: Connections for the RX0 Pin

3.9 UART1 (TX1/RX1)

The TX1 and RX1 pins can be used for a regular serial interface (by connecting a RS-232 transceiver for example), or they can be used to directly operate optical components (for example, an infrared diode and phototransistor implementing a FLAG interface).

3.10 Connecting V1 and Reset Pins

A voltage divider should be used to establish that V1 is in a safe range (see Figure 15). V1 must be lower than 2.9 V in all cases in order to keep the hardware watchdog timer enabled. A series 5 k Ω resistor (R3) and a capacitor to ground (C1) are added for enhanced EMC immunity. The parallel impedance of R1 and R2 should be approximately 8 k Ω to 10 k Ω in order to provide hysteresis for the power fault monitor.

Figure 15: Voltage Divider for V1

Even though a functional power and measurement unit will not necessarily need a reset switch, it is useful to have a reset pushbutton switch for prototyping, as shown in Figure 16, left side. The RESET signal may be sourced from V3P3SYS, or VBAT (if a battery is present), or from a combination of these sources, depending on the application.

For production, the RESET pin should be protected by the external components shown in Figure 16, right side. R₁ should be in the range of 100 Ω and mounted as closely as possible to the IC. The RESET pin can also be directly connected to ground.

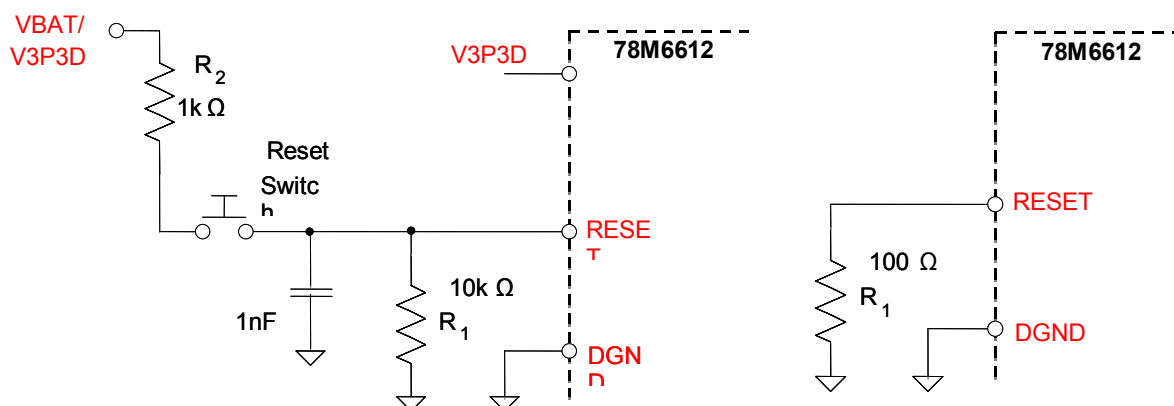

Figure 16: External Components for RESET: Development Circuit (Left), Production Circuit (Right)
