

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

FEATURES

- PLL-generated clock or direct master clock**
- Low EMI design**
- 112 dB DAC/107 dB ADC dynamic range and SNR**
- 96 dB THD + N**
- Single 3.3 V supply**
- Tolerance for 5 V logic inputs**
- Supports 24-bits and 8 kHz to 192 kHz sample rates**
- Differential ADC input**
- Differential DAC output**
- Log volume control with autoramp function**
- I²C-controllable for flexibility**
- Software-controllable clickless mute**
- Software power-down**
- Right-justified, left-justified, I²S, and TDM modes**
- Master and slave modes up to 16-channel input/output**
- Available in a 64-lead LQFP**
- Qualified for automotive applications**

APPLICATIONS

- Automotive audio systems**
- Home theater systems**
- Set-top boxes**
- Digital audio effects processors**

GENERAL DESCRIPTION

The AD1937 is a high performance, single-chip codec that provides four analog-to-digital converters (ADCs) with differential input and eight digital-to-analog converters (DACs) with differential output, using the Analog Devices, Inc., patented multibit sigma-delta (Σ - Δ) architecture. An I²C[®] port is included, allowing a microcontroller to adjust volume and many other parameters. The AD1937 operates from 3.3 V digital and analog supplies. The AD1937 is available in a 64-lead (differential output) LQFP.

The AD1937 is designed for low EMI. This consideration is apparent in both the system and circuit design architectures. By using the on-board PLL to derive the master clock from the LR (frame) clock or from an external crystal, the AD1937 eliminates the need for a separate high frequency master clock and can also be used with a suppressed bit clock. The DACs and ADCs are designed using the latest Analog Devices continuous time architecture to further minimize EMI. By using 3.3 V supplies, power consumption is minimized and further reduces emissions.

SPECIFICATIONS

TEST CONDITIONS

Performance of all channels is identical, exclusive of the interchannel gain mismatch and interchannel phase deviation specifications.

Table 1.

Parameter	Value
Supply Voltages (AVDD, DVDD)	3.3 V
Temperature	As specified in Table 2 and Table 3
Master Clock	12.288 MHz (48 kHz f_s , 256 × f_s mode)
Input Sample Rate	48 kHz
Measurement Bandwidth	20 Hz to 20 kHz
Word Width	24 bits
Load Capacitance (Digital Output)	20 pF
Load Current (Digital Output)	±1 mA or 1.5 kΩ to ½ DVDD supply
Input Voltage High	2.0 V
Input Voltage Low	0.8 V

ANALOG PERFORMANCE SPECIFICATIONS

Specifications guaranteed at a T_A of 25°C.

ABSOLUTE MAXIMUM RATINGS

Table 9.

Parameter	Rating
Analog (AVDD)	-0.3 V to +3.6 V
Digital (DVDD)	-0.3 V to +3.6 V
VSUPPLY	-0.3 V to +6.0 V
Input Current (Except Supply Pins)	±20 mA
Analog Input Voltage (Signal Pins)	-0.3 V to AVDD + 0.3 V
Digital Input Voltage (Signal Pins)	-0.3 V to DVDD + 0.3 V
Operating Temperature Range (Case)	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} represents junction-to-ambient thermal resistance;
 θ_{JC} represents the junction-to-case thermal resistance.
 All characteristics are for a 4-layer board.

Table 10.

Package Type	θ_{JA}	θ_{JC}	Unit
64-Lead LQFP	47	11.1	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

THEORY OF OPERATION

ANALOG-TO-DIGITAL CONVERTERS (ADCs)

There are four ADC channels in the AD1937 configured as two stereo pairs with differential inputs. The ADCs can operate at a nominal sample rate of 48 kHz, 96 kHz, or 192 kHz. The ADCs include on-board digital antialiasing filters with 79 dB stop-band attenuation and linear phase response, operating at an oversampling ratio of 128 (48 kHz, 96 kHz, and 192 kHz modes). Digital outputs are supplied through two serial data output pins (one for each stereo pair): a common frame clock (ALRCLK) and a common bit clock (ABCLK). Alternatively, the TDM modes can be used to access up to 16 channels on a single TDM data line.

The ADCs must be driven from a differential signal source for best performance. The input pins of the ADCs connect to internal switched capacitors. To isolate the external driving op amp from the glitches caused by the internal switched capacitors, each input pin should be isolated by using a series-connected external 100 Ω resistor and a 1 nF capacitor connected from each input to ground. Use a high quality capacitor such as a ceramic NP0/C0G, or polypropylene film.

The differential inputs have a nominal common-mode voltage of 1.5 V. The voltage at the common-mode reference pin (CM) can be used to bias external op amps to buffer the input signals (see the Power Supply and Voltage Reference section). The inputs can also be ac-coupled and in that case do not need an external dc bias to CM.

A digital high-pass filter can be switched in line with the ADCs (ADC Control 0 Register) to remove residual dc offsets. It has a 1.4 Hz, 6 dB per octave cutoff at a 48 kHz sample rate. The cutoff frequency scales directly with sample frequency.

DIGITAL-TO-ANALOG CONVERTERS (DACs)

The AD1937 DAC channels are arranged in four stereo pairs, giving eight analog outputs; the outputs are differential for improved noise and distortion performance. The DACs include on-board digital reconstruction filters with 70 dB stop-band attenuation and linear phase response, operating at an oversampling ratio of 4 (48 kHz or 96 kHz modes) or 2 (192 kHz mode). Each channel has its own independently programmable attenuator, adjustable in 255 steps in increments of 0.375 dB. Digital inputs are supplied through four serial data input pins (one for each stereo pair), a common frame clock (DLRCLK), and a common bit clock (DBCLK). Alternatively, one of the TDM modes can be used to access up to 16 channels on a single TDM data line.

Each output pin has a nominal common-mode dc level of 1.5 V and swings ± 1.27 V for a 0 dBFS digital input signal. A single op amp, third-order, external, low-pass filter is recommended to remove high frequency noise present on the output pins, as well as to provide a differential-to-single-ended conversion for the differential output. Note that the use of op amps with low slew rates or low bandwidth can cause high frequency noise and tones to fold down into the audio band; exercise care in selecting these components.

The voltage at CM can be used to bias the external op amps that buffer the output signals (see the Power Supply and Voltage Reference section).

CLOCK SIGNALS

The on-chip phase-locked loop (PLL) can be selected to reference the input sample rate from either of the LRCLK pins or 256 \times , 384 \times , 512 \times , or 768 \times sample rate s (f_s), referenced to the 48 kHz mode from the MCLKI/MCLKXI pin. The default at power-up is 256 $\times f_s$ from the MCLKI/MCLKXI pin. In 96 kHz mode, the master clock frequency stays at the same absolute frequency; therefore, the actual multiplication rate is divided by 2. In 192 kHz mode, the actual multiplication rate is divided by 4. For example, if the AD1937 is programmed in 256 $\times f_s$ mode, the frequency of the master clock input is 256 \times 48 kHz = 12.288 MHz. If the AD1937 is then switched to 96 kHz operation (by writing to the I²C port), the frequency of the master clock should remain at 12.288 MHz, which is 128 $\times f_s$ in this example. In 192 kHz mode, this becomes 64 $\times f_s$.

The internal clock for the ADCs is 256 $\times f_s$ for all clock modes. The internal clock for the DACs varies by mode: 512 $\times f_s$ (48 kHz mode), 256 $\times f_s$ (96 kHz mode), or 128 $\times f_s$ (192 kHz mode). By default, the on-board PLL generates this internal master clock from an external clock. A direct 512 $\times f_s$ (referenced to 48 kHz mode) master clock can be used for either the ADCs or DACs, if selected in the PLL and Clock Control 1 register.

Note that it is not possible to use a direct clock for the ADCs set to the 192 kHz mode. It is required that the on-chip PLL be used in this mode.

The PLL can be powered down in the PLL and Clock Control 0 Register. To ensure reliable locking when changing PLL modes, or if the reference clock is unstable at power-on, power down the PLL and then power it back up after the reference clock has stabilized.

The internal master clock (MCLK) can be disabled in the PLL and Clock Control 0 register to reduce power dissipation when the AD1937 is idle. The clock should be stable before it is enabled. Unless a standalone mode is selected (see the I²C Control Port section), the clock is disabled by reset and must be enabled by writing to the I²C port for normal operation.

AD1937

To maintain the highest performance possible, limit the clock jitter of the internal master clock signal to less than a 300 ps rms time interval error (TIE). Even at these levels, extra noise or tones can appear in the DAC outputs if the jitter spectrum contains large spectral peaks. If the internal PLL is not used, it is best to use an independent crystal oscillator to generate the master clock. In addition, it is especially important that the clock signal not pass through an FPGA, CPLD, or other large digital chip (such as a DSP) before being applied to the AD1937. In most cases, this induces clock jitter due to the sharing of common power and ground connections with other unrelated digital output signals. When the PLL is used, jitter in the reference clock is attenuated above a certain frequency depending on the loop filter.

RESET AND POWER-DOWN

The function of the $\overline{\text{PD/RST}}$ pin sets all the control registers to their default settings. To avoid audio pops, $\overline{\text{PD/RST}}$ does not power down the analog outputs. After $\overline{\text{PD/RST}}$ is deasserted and the PLL acquires lock condition, an initialization routine runs inside the AD1937. This initialization lasts for approximately 256 master clock cycles. Once the routine is complete, the registers can be programmed.

The power-down bits in the PLL and Clock Control 0, DAC Control 1, and ADC Control 1 registers power down their respective sections. All other register settings are retained. To guarantee proper startup, the $\overline{\text{PD/RST}}$ pin should be pulled low by an external resistor.

I²C CONTROL PORT

The AD1937 has an I²C-compatible control port that permits programming and reading back the internal control registers for the ADCs, DACs, and clock system. There is also a stand-alone mode available for operation without serial control, configured at reset using the serial control pins. All registers are set to default except internal MCLK enable, which is set to 1 and ADC BCLK and LRCLK master/slave is set by SDA (see Table 12 for details).

Table 12. Hardware Selection of Standalone Mode

ADC Clocks	ADDR0 (Pin 30)	SDA (Pin 31)	SCL (Pin 34)	ADDR1 (Pin 35)
Slave	0	0	0	0
Master	0	1	0	0

The I²C interface of the AD1937 is a 2-wire interface that consists of a clock line (SCL) and a data line (SDA). SDA is bidirectional and the AD1937 drives SDA either to acknowledge the master (ACK) or to send data during a read operation. The SDA pin for the I²C port is an open-drain collector and requires a 2 k Ω pull-up resistor. A write or read access occurs when the SDA line is pulled low while the SCL line is high, indicated by start in the timing diagrams. SDA is only allowed to change when SCL is low except when a start or stop condition occurs, as shown in Figure 13 and Figure 14. The first eight bits of the data-word consist of the device address and the R/W bit. The device address consists of an internal built-in address (0x08) ORed with the two address bits, ADDR1 and ADDR0, and the R/W bit. The two address bits allow four AD1937s to be used in a system. Tie I²C ADDR0 and ADDR1 low or high and program the ADDR bits accordingly as 0 or 1. Initiating a write operation to the AD1937 involves sending a start condition and then sending the device address with the R/W bit set low. The AD1937 responds by issuing an acknowledge to indicate that it has been addressed. The user then sends a second frame telling the AD1937 which register is required to be written to. Another acknowledge is issued by the AD1937. Finally, the user can send another frame with the eight data bits required to be written to the register. A third acknowledge is issued by the AD1937 after which the user can send a stop condition to complete the data transfer.

A read operation requires that the user first write to the AD1937 to point to the correct register and then read the data. This is achieved by sending a start condition followed by the device address frame, with the R/W bit low; the AD1937 returns an acknowledge. The master then sends the register address frame. Following the acknowledge from the AD1937, the user must issue a repeated start condition. The next frame is the device address with the R/W bit set high; the AD1937 returns an acknowledge. On the next frame, the AD1937 outputs the register data on the SDA line; the master should send an acknowledge. A stop condition completes the read operation. Figure 13 and Figure 14 show examples of writing to and reading from the DAC1L volume control register, Address 0x06 (see Table 28).

POWER SUPPLY AND VOLTAGE REFERENCE

The AD1937 is designed for a 3.3 V supply. Separate power supply pins are provided for the analog and digital sections. To minimize noise pickup, these pins should be bypassed with 100 nF ceramic chip capacitors placed as close to the pins as possible. A bulk aluminum electrolytic capacitor of at least 22 μ F should also be provided on the same printed circuit board (PCB) as the codec. For critical applications, improved performance is obtained with separate supplies for the analog and digital sections. If this is not possible, it is recommended that the analog and digital load pins be isolated by means of a ferrite bead in series with the supply. It is important that the analog supply be as clean as possible.

The AD1937 includes a 3.3 V regulator driver that only requires an external pass transistor, a resistor, and bypass capacitors to turn a 5 V supply into 3.3 V. If the regulator driver is not used, connect VSUPPLY, VDRIVE, and VSENSE to DGND.

All digital inputs are compatible with TTL and CMOS levels. All outputs are driven from the 3.3 V DVDD supply and are compatible with TTL and 3.3 V CMOS levels.

The ADC and DAC internal analog voltage reference (V_{REF}) is brought out on the FILTR pin and should be bypassed as close as possible to the chip with a parallel combination of 10 μ F and 100 nF capacitors. Any external current drawn should be limited to less than 50 μ A.

The internal reference can be disabled in the PLL and Clock Control 1 register, and FILTR can be driven from an external source. This can be used to scale the DAC output to the clipping level of a power amplifier based on its power supply voltage. The ADC input gain varies by the inverse ratio. It is not advisable to drive the FILTR pin with more than $(AVDD/2)$ V. The total gain from ADC input to DAC output remains constant.

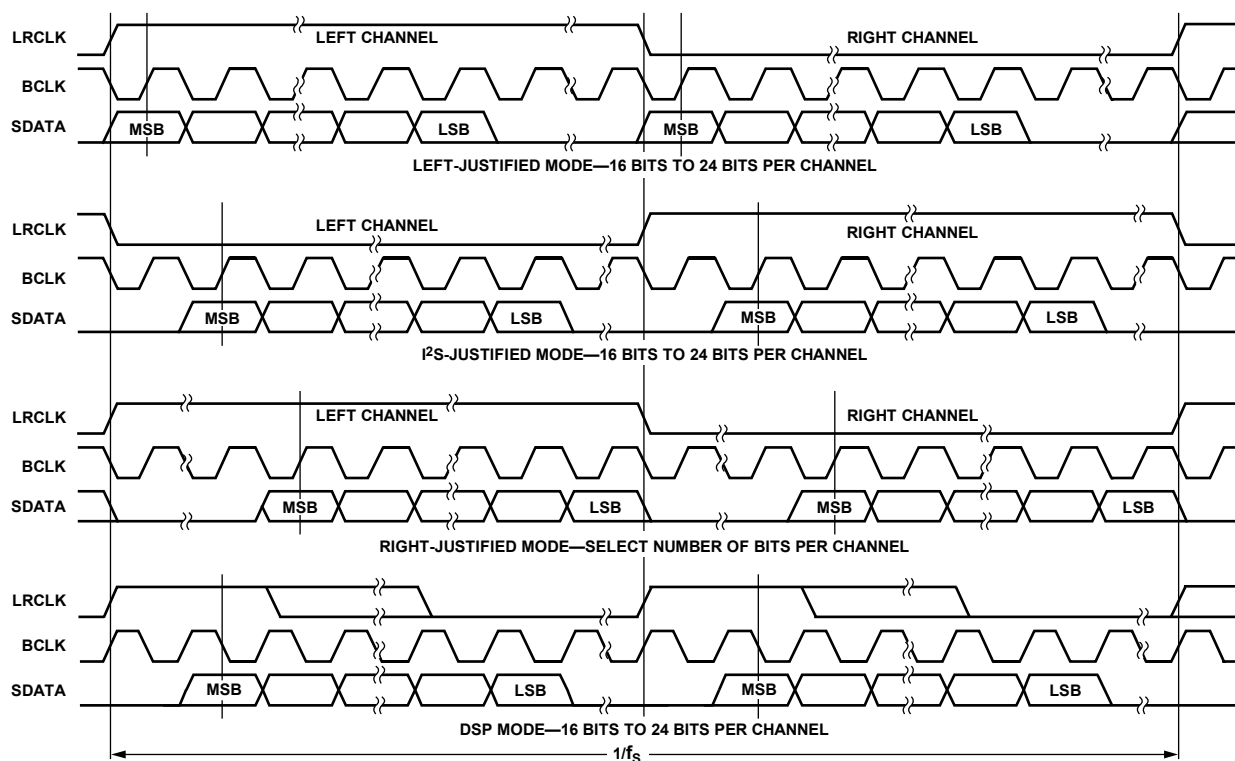

The CM pin should be bypassed as close as possible to the chip, with a parallel combination of 47 μ F and 100 nF capacitors. This voltage can be used to bias external op amps to the common-mode voltage of the input and output signal pins. The output current should be limited to less than 0.5 mA source and 2 mA sink.

SERIAL DATA PORTS—DATA FORMAT

The eight DAC channels use a common serial bit clock (DBCLK) and a common left-right framing clock (DLRCLK) in the serial data port. The four ADC channels use a common serial bit clock (ABCLK) and left-right framing clock (ALRCLK) in the serial data port. The clock signals are all synchronous with the sample rate. The normal stereo serial modes are shown in Figure 15.

The ADC and DAC serial data modes default to I²S stereo. The ports can also be programmed for left-justified stereo, right-justified stereo, and TDM modes. The word width is

24 bits by default and can be set to 16 or 20 bits in the DAC Control 2 and ADC Control 1 registers. The DAC serial formats are programmable in the DAC Control 0 register. The polarity of DBCLK and DLRCLK is programmable in the DAC Control 1 register. The ADC serial format is programmable in ADC Control 1 register. The ABCLK and ALRCLK clock polarities are programmed in ADC Control 2 register. In Figure 2, Figure 3, and Figure 15 all of the clocks are shown with their normal polarity. Both DAC and ADC serial ports can be programmed to become the bus masters according to DAC Control 1 and ADC Control 2 registers. By default, both ADC and DAC serial ports are in the slave mode.

NOTES

1. DSP MODE DOES NOT IDENTIFY CHANNEL.
2. LRCLK NORMALLY OPERATES AT f_s EXCEPT FOR DSP MODE, WHICH IS $2 \times f_s$.
3. BCLK FREQUENCY IS NORMALLY $64 \times$ LRCLK BUT MAY BE OPERATED IN BURST MODE.

TIME-DIVISION MULTIPLEXED (TDM) MODES

The serial ports of the AD1937 have several different TDM serial data modes. Single-line TDM mode is the most commonly used configuration (see Figure 16 and Figure 17).

These figures show 8-channel configuration; other possible options are 4- and 16-channel configurations. In Figure 16, the eight on-chip DAC data slots are packed into one I²S TDM stream. In this mode, both DBCLK and ABCLK are 256 fs. In Figure 17, the ADC serial port outputs one data stream consisting of four on-chip ADCs followed by four unused slots.

Figure 16. Single-Line TDM Mode 8-Channel DAC Configuration

Figure 17. Single-Line TDM Mode 8-Channel ADC Configuration

The I/O pin functions of the serial ports are defined according to the serial mode that is selected. For a detailed description of the function of each pin in TDM and TDM/AUX modes, see Table 18.

The AD1937 allows systems with more than eight DAC channels to be easily configured by the use of an auxiliary serial data port. The TDM/AUX mode 16-channel configuration is shown in Figure 18. In this mode, the AUX channels are the last four slots of the TDM data stream. These slots are extracted and output to the AUX serial port. It should be noted that due to the high DBCLK frequency, this mode is available only in the 48 kHz/44.1 kHz/32 kHz sample rates. An 8-channel DAC configuration cannot be TDM/AUX because there are no extra data slots for the AUX packets; this would be single-line TDM mode.

The AD1937 also allows system configurations with more than four ADC channels as shown in Figure 19 (using 8 ADCs) and Figure 20 (using 16 ADCs). Due to the high ABCLK frequency, this mode is available only in the 48 kHz/44.1 kHz/32 kHz sample rates.

Combining the TDM/AUX ADC and DAC modes results in a system configuration of 8 ADCs and 12 DACs. The system, then consists of two external stereo ADCs, two external stereo DACs, and one AD1937. This mode is shown in Figure 21 (combined TDM/AUX DAC and ADC modes).

In the TDM/AUX mode, the frame sync (ALRLCK) triggers the TDM word by crossing the high frequency TDM BCLK (ABCLK) to 0, similar to the single-line TDM modes (see Figure 16 and Figure 17). The AUX LRCLK (DLRLCK) runs at the much slower fs of the AUX port; the AUX BCLK (DBCLK) runs at 64 × fs. This is shown in the TDM/AUX figures (see Figure 18 to Figure 21).

Table 18. Pin Function Changes in TDM and TDM/AUX Modes

Mnemonic	Stereo Modes	TDM Modes	TDM/AUX Modes
ASDATA1	ADC1 data out	TDM ADC data out	TDM data out
ASDATA2	ADC2 data out	TDM ADC data in	AUX DAC1 data out (to external DAC1)

DAISY-CHAIN MODE

The AD1937 also allows a daisy-chain configuration to expand the system to 16 DACs and 8 ADCs (see Figure 22 to Figure 26). In this mode, the DBCLK frequency is $512 \times f_s$. The first eight slots of the TDM DAC data stream belong to the first AD1937 in the chain and the last eight slots belong to the second AD1937. The second AD1937 is the device attached to the DSP TDM port.

To accommodate 16 channels at a 96 kHz sample rate, the AD1937 can be configured into a dual-line, TDM mode as shown in Figure 23. This mode allows a slower DBCLK than normally required by the one-line TDM mode. The first four channels of each TDM input belong to the first AD1937 in the chain and the last four channels belong to the second AD1937.

The dual-line TDM mode can also be used to send data at a 192 kHz sample rate into the AD1937, as shown in Figure 24.

There are two configurations for the ADC port to work in daisy-chain mode. The first configuration is with an ABCLK at $256 \times f_s$, see Figure 25. The second configuration is with an ABCLK at $512 \times f_s$, see Figure 26. Note that in the $512 \times f_s$ ABCLK mode, the ADC channels occupy the first eight slots; the second eight slots are empty. The TDM ADC data in (ASDATA2) port of the first AD1937 must be grounded in all modes of operation.

The I/O pins of the serial ports are defined according to the serial mode selected. See Table 19 for a detailed description of the function of each pin. See Figure 27 for a typical AD1937 configuration with two external stereo DACs and two external stereo ADCs.
