## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## Data Sheet

## FEATURES

```
Extremely low harmonic distortion
    -102 dBc HD2 at 10 MHz
    -83 dBc HD2 at 70 MHz
    -77 dBc HD2 at 100 MHz
    -101 dBc HD3 at }10\textrm{MHz
    -97 dBc HD3 at 70 MHz
    -91 dBc HD3 at }100\textrm{MHz
Low input voltage noise: 2.3 nV/\sqrt{}{Hz}
High speed
    -3 dB bandwidth of 1.4 GHz, G = 2
    Slew rate: 6800 V/\mus, 25% to 75%
    Fast overdrive recovery of <1 ns
\pm0.5 mV typical offset voltage
Externally adjustable gain
Stable for differential gains \geq2
Differential-to-differential or single-ended-to-differential
    operation
```

Adjustable output common-mode voltage
Single-supply operation: 3.3 V to 5 V

## APPLICATIONS

## ADC drivers

Single-ended-to-differential converters
IF and baseband gain blocks
Differential buffers
Line drivers

## GENERAL DESCRIPTION

The ADA4939-1/ADA4939-2 are low noise, ultralow distortion, high speed differential amplifiers. They are an ideal choice for driving high performance ADCs with resolutions up to 16 bits from dc to 100 MHz . The output common-mode voltage is user adjustable by means of an internal common-mode feedback loop, allowing the ADA4939-1/ADA4939-2 output to match the input of the ADC. The internal feedback loop also provides exceptional output balance as well as suppression of even-order harmonic distortion products.
With the ADA4939-1/ADA4939-2, differential gain configurations are easily realized with a simple external feedback network of four resistors that determine the closed-loop gain of the amplifier.
The ADA4939-1/ADA4939-2 are fabricated using Analog Devices, Inc., proprietary silicon-germanium (SiGe), complementary bipolar process, enabling them to achieve very low levels of distortion with an input voltage noise of only $2.3 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. The low dc offset and excellent dynamic performance of the ADA4939-1/ADA4939-2 make them well suited for a wide variety of data acquisition and signal processing applications.

[^0]
## FUNCTIONAL BLOCK DIAGRAMS

Figure 2. ADA4939-2
The ADA4939-1 (single) is available in a $3 \mathrm{~mm} \times 3 \mathrm{~mm}$, 16-lead LFCSP, and the ADA4939-2 (dual) is available in a $4 \mathrm{~mm} \times 4 \mathrm{~mm}$, 24-lead LFCSP. The pinouts are optimized to facilitate printed circuit board (PCB) layout and minimize distortion. The ADA4939-1/ADA4939-2 are specified to operate over the $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ temperature range; both operate on supplies between 3.3 V and 5 V .

## ABSOLUTE MAXIMUM RATINGS

Table 7.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage | 5.5 V |
| Power Dissipation | See Figure 4 |
| Input Current, $+\mathrm{IN},-\mathrm{IN}, \overline{\mathrm{PD}}$ | $\pm 5 \mathrm{~mA}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Operating Temperature Range |  |
| $\quad$ ADA4939-1 | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| $\quad$ ADA4939-2 | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec) | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

$\theta_{\text {JA }}$ is specified for the device (including exposed pad) soldered to a high thermal conductivity 2 s 2 p circuit board, as described in EIA/JESD 51-7.

Table 8. Thermal Resistance

| Package Type | $\boldsymbol{\theta}_{\text {JA }}$ | Unit |
| :--- | :--- | :--- |
| ADA4939-1, 16-Lead LFCSP (Exposed Pad) | 98 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| ADA4939-2, 24-Lead LFCSP (Exposed Pad) | 67 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## MAXIMUM POWER DISSIPATION

The maximum safe power dissipation for the ADA4939-1/ ADA4939-2 package is limited by the associated rise in junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$ on the die. At approximately $150^{\circ} \mathrm{C}$, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit can change the stresses that the package exerts on the die, permanently shifting the parametric performance of the ADA4939-1/ ADA4939-2. Exceeding a junction temperature of $150^{\circ} \mathrm{C}$ for an extended period can result in changes in the silicon devices, potentially causing failure.

The power dissipated in the package $\left(\mathrm{P}_{\mathrm{D}}\right)$ is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive. The quiescent power is the voltage between the supply pins ( $\mathrm{V}_{\mathrm{s}}$ ) times the quiescent current $\left(\mathrm{I}_{\mathrm{s}}\right)$. The power dissipated due to the load drive depends upon the particular application. Calculate the power due to the load drive by multiplying the load current by the associated voltage drop across the device. RMS voltages and currents must be used in these calculations.

Airflow increases heat dissipation, effectively reducing $\theta_{\mathrm{JA}}$. In addition, more metal directly in contact with the package leads/ exposed pad from metal traces, through holes, ground, and power planes reduces $\theta_{\text {JA }}$.

Figure 4 shows the maximum safe power dissipation in the package vs. the ambient temperature for the single 16 -lead $\operatorname{LFCSP}\left(98^{\circ} \mathrm{C} / \mathrm{W}\right)$ and the dual 24 -lead LFCSP $\left(67^{\circ} \mathrm{C} / \mathrm{W}\right)$ on a JEDEC standard 4-layer board with the exposed pad soldered to a PCB pad that is connected to a solid plane.

Figure 4. Maximum Power Dissipation vs. Ambient Temperature for a 4-Layer Board

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## OPERATIONAL DESCRIPTION

## DEFINITION OF TERMS

Figure 42. Circuit Definitions

## Differential Voltage

Differential voltage refers to the difference between two node voltages. For example, the output differential voltage (or equivalently, output differential-mode voltage) is defined as

$$
V_{\text {OUT, } d m}=\left(V_{+ \text {OUT }}-V_{- \text {OUT }}\right)
$$

where $V_{+ \text {out }}$ and $V_{\text {-out }}$ refer to the voltages at the +OUT and -OUT terminals with respect to a common reference.

## Common-Mode Voltage

Common-mode voltage refers to the average of two node voltages. The output common-mode voltage is defined as

$$
V_{\text {OUT }, \text { cm }}=\left(V_{+ \text {out }}+V_{-O U T}\right) / 2
$$

## Balance

Output balance is a measure of how close the differential signals are to being equal in amplitude and opposite in phase. Output balance is most easily determined by placing a well-matched resistor divider between the differential voltage nodes and comparing the magnitude of the signal at the divider midpoint with the magnitude of the differential signal (see Figure 39). By this definition, output balance is the magnitude of the output common-mode voltage divided by the magnitude of the output differential mode voltage.

Output Balance Error $=\left|\frac{V_{\text {OUT }, c m}}{V_{\text {OUT }, d m}}\right|$

## THEORY OF OPERATION

The ADA4939-1/ADA4939-2 differ from conventional op amps in that they have two outputs whose voltages move in opposite directions and an additional input, Vocm. Like op amps, they rely on high open-loop gain and negative feedback to force these outputs to the desired voltages. The ADA4939-1/ ADA4939-2 behave much like standard voltage feedback op amps and facilitate single-ended-to-differential conversions, common-mode level shifting, and amplifications of differential signals. Like op amps, the ADA4939-1/ADA4939-2 have high input impedance and low output impedance. Because they use voltage feedback, the ADA4939-1/ADA4939-2 manifest a nominally constant gain-bandwidth product.

Two feedback loops are employed to control the differential and common-mode output voltages. The differential feedback, set with external resistors, controls only the differential output voltage. The common-mode feedback controls only the common-mode output voltage. This architecture makes it easy to set the output common-mode level to any arbitrary value within the specified limits. The output common-mode voltage is forced by the internal common-mode feedback loop to be equal to the voltage applied to the Voсм input.
The internal common-mode feedback loop produces outputs that are highly balanced over a wide frequency range without requiring tightly matched external components. This results in differential outputs that are very close to the ideal of being identical in amplitude and are exactly $180^{\circ}$ apart in phase.

## ANALYZING AN APPLICATION CIRCUIT

The ADA4939-1/ADA4939-2 use high open-loop gain and negative feedback to force their differential and common-mode output voltages in such a way as to minimize the differential and common-mode error voltages. The differential error voltage is defined as the voltage between the differential inputs labeled + IN and -IN (see Figure 42). For most purposes, this voltage is zero. Similarly, the difference between the actual output common-mode voltage and the voltage applied to Vосм is also zero. Starting from these two assumptions, any application circuit can be analyzed.

## SETTING THE CLOSED-LOOP GAIN

The differential-mode gain of the circuit in Figure 42 can be determined by

$$
\left|\frac{V_{\text {OUT, dm }}}{V_{I N, d m}}\right|=\frac{R_{F}}{R_{G}}
$$

This presumes that the input resistors $\left(\mathrm{R}_{\mathrm{G}}\right)$ and feedback resistors $\left(\mathrm{R}_{\mathrm{F}}\right)$ on each side are equal.

## STABLE FOR GAINS $\geq \mathbf{2}$

The ADA4939-1/ADA4939-2 frequency response exhibits excessive peaking for differential gains $<2$; therefore, operate the devioce with differential gains $\geq 2$.

## ESTIMATING THE OUTPUT NOISE VOLTAGE

To estimate the differential output noise of the ADA4939-1/ ADA4939-2 use the noise model shown in Figure 43. The inputreferred noise voltage density, $\mathrm{v}_{\mathrm{nIN}}$, is modeled as a differential input, and the noise currents, $i_{\mathrm{nIN}-}$ and $\mathrm{i}_{\mathrm{nIN}+}$, appear between each input and ground. The output voltage due to $\mathrm{v}_{\mathrm{nIN}}$ is obtained by multiplying $\mathrm{v}_{\mathrm{nIN}}$ by the noise gain, $\mathrm{G}_{\mathrm{N}}$ (defined in the $\mathrm{G}_{\mathrm{N}}$ equation that follows). The noise currents are uncorrelated with the same mean-square value, and each produces an output voltage that is equal to the noise current multiplied by the associated feedback resistance. The noise voltage density at the Vocm/Vосмх pin is $\mathrm{V}_{\mathrm{ncm}}$. When the feedback networks have the same feedback factor, as in most cases, the output noise due to $\mathrm{V}_{\mathrm{nCM}}$ is commonmode. Each of the four resistors contributes $\left(4 \mathrm{kTR}_{\mathrm{xx}}\right)^{1 / 2}$. The noise from the feedback resistors appears directly at the output, and the noise from the gain resistors appears at the output multiplied by $\mathrm{R}_{\mathrm{Fx}} / \mathrm{R}_{\mathrm{Gx}}$. Table 11 summarizes the input noise sources, the multiplication factors, and the output-referred noise density terms.

Figure 43. Noise Model

${ }^{1} R_{G 2}=R_{G 1}+\left(R_{S} \| R_{T}\right)$.

Similar to the case of a conventional op amp, the output noise voltage densities can be estimated by multiplying the inputreferred terms at +IN and -IN by the appropriate output factor, where:
$G_{N}=\frac{2}{\left(\beta_{1}+\beta_{2}\right)}$ is the circuit noise gain.
$\beta_{1}=\frac{R_{G 1}}{R_{F 1}+R_{G 1}}$ and $\beta_{2}=\frac{R_{G 2}}{R_{F 2}+R_{G 2}}$ are the feedback factors.
When the feedback factors are matched, $\mathrm{R}_{\mathrm{F} 1} / \mathrm{R}_{\mathrm{G} 1}=\mathrm{R}_{\mathrm{F} 2} / \mathrm{R}_{\mathrm{G} 2}, \beta 1=$ $\beta 2=\beta$, and the noise gain becomes

$$
G_{N}=\frac{1}{\beta}=1+\frac{R_{F}}{R_{G}}
$$

Note that the output noise from Vосм goes to zero in this case. The total differential output noise density, $\mathrm{v}_{\mathrm{nOD}}$, is the root-sumsquare of the individual output noise terms.

$$
v_{n O D}=\sqrt{\sum_{i=1}^{8} v_{n O i}^{2}}
$$

Table 12 and Table 13 list several common gain settings, associated resistor values, input impedance, and output noise density for both balanced and unbalanced input configurations.

## IMPACT OF MISMATCHES IN THE FEEDBACK NETWORKS

As previously mentioned, even if the external feedback networks $\left(\mathrm{R}_{\mathrm{F}} / \mathrm{R}_{\mathrm{G}}\right)$ are mismatched, the internal common-mode feedback loop still forces the outputs to remain balanced. The amplitudes of the signals at each output remain equal and $180^{\circ}$ out of phase. The input-to-output differential mode gain varies proportionately to the feedback mismatch, but the output balance is unaffected.

The gain from the $V_{\text {осм }} / V_{\text {осмх }}$ pin to $V_{O, d m}$ is equal to

$$
2(\beta 1-\beta 2) /(\beta 1+\beta 2)
$$

When $\beta 1=\beta 2$, this term goes to zero and there is no differential output voltage due to the voltage on the Vосм input (including noise). The extreme case occurs when one loop is open and the other has $100 \%$ feedback; in this case, the gain from Vосм input to $\mathrm{V}_{\mathrm{O}, \mathrm{dm}}$ is either +2 or -2 , depending on which loop is closed. The feedback loops are nominally matched to within $1 \%$ in most applications, and the output noise and offsets due to the V $\mathrm{V}_{\text {осм }}$ input are negligible. If the loops are intentionally mismatched by a large amount, it is necessary to include the gain term from V Oсм $^{\text {a }}$ to $\mathrm{V}_{\mathrm{o}, \mathrm{dm}}$ and account for the extra noise. For example, if $\beta 1=0.5$ and $\beta 2=0.25$, the gain from $V_{\text {ocm }}$ to $V_{o, d m}$ is 0.67 . If the $\mathrm{V}_{\text {осм }} / \mathrm{V}_{\text {осмх }}$ pin is set to 2.5 V , a differential offset voltage is present at the output of $(2.5 \mathrm{~V})(0.67)=1.67 \mathrm{~V}$. The differential output noise contribution is $(7.5 \mathrm{nV} / \sqrt{ } \mathrm{Hz})(0.67)=5 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. Both of these results are undesirable in most applications; therefore, it is best to use nominally matched feedback factors.

Mismatched feedback networks also result in a degradation of the ability of the circuit to reject input common-mode signals, much the same as for a four-resistor difference amplifier made from a conventional op amp.
As a practical summarization of the above issues, resistors of $1 \%$ tolerance produce a worst-case input CMRR of approximately 40 dB , a worst-case differential-mode output offset of 25 mV due to a 2.5 V Vосм input, negligible Vосм noise contribution, and no significant degradation in output balance error.

## CALCULATING THE INPUT IMPEDANCE FOR AN APPLICATION CIRCUIT

The effective input impedance of a circuit depends on whether the amplifier is being driven by a single-ended or differential signal source. For balanced differential input signals, as shown in Figure 44, the input impedance ( $\mathrm{R}_{\mathrm{IN}, \mathrm{dm}}$ ) between the inputs $\left(+D_{\text {IN }}\right.$ and $\left.-D_{\text {IN }}\right)$ is simply $R_{\text {IN }, d m}=2 \times R_{G}$.

Figure 44. ADA4939-1/ADA4939-2 Configured for Balanced (Differential) Inputs
For an unbalanced, single-ended input signal (see Figure 45), the input impedance is

$$
R_{I N, S E}=\left(\frac{R_{G}}{1-\frac{R_{F}}{2 \times\left(R_{G}+R_{F}\right)}}\right)
$$

Figure 45. ADA4939-1/ADA4939-2 with Unbalanced (Single-Ended) Input

The input impedance of the circuit is effectively higher than it would be for a conventional op amp connected as an inverter because a fraction of the differential output voltage appears at the inputs as a common-mode signal, partially bootstrapping the voltage across the input resistor $\mathrm{R}_{\mathrm{G}}$. The common-mode voltage at the amplifier input terminals can be easily determined by noting that the voltage at the inverting input is equal to the noninverting output voltage divided down by the voltage divider formed by $\mathrm{R}_{\mathrm{F}}$ and $\mathrm{R}_{\mathrm{G}}$ in the lower loop. This voltage is present at both input terminals due to negative voltage feedback and is in phase with the input signal, thus reducing the effective voltage across $\mathrm{R}_{\mathrm{G}}$ in the upper loop and partially bootstrapping $\mathrm{R}_{\mathrm{G}}$.

## Terminating a Single-Ended Input

This section deals with how to properly terminate a single-ended input to the ADA4939-1/ADA4939-2 with a gain of $2, \mathrm{R}_{\mathrm{F}}=400 \Omega$, and $R_{G}=200 \Omega$. An example using an input source with a terminated output voltage of 1 V p-p and source resistance of $50 \Omega$ illustrates the four simple steps that must be followed. Note that, because the terminated output voltage of the source is 1 V p-p, the open circuit output voltage of the source is 2 V p-p. The source shown in Figure 46 indicates this open-circuit voltage.

1. The input impedance must be calculated using the formula

$$
R_{I N}=\left(\frac{R_{G}}{1-\frac{R_{F}}{2 \times\left(R_{G}+R_{F}\right)}}\right)=\left(\frac{200}{1-\frac{400}{2 \times(200+400)}}\right)=300 \Omega
$$

Figure 46. Calculating Single-Ended Input Impedance $R_{I N}$

## ADA4939-1/ADA4939-2

2. To match the $50 \Omega$ source resistance, the termination resistor, $\mathrm{R}_{\mathrm{T}}$, is calculated using $\mathrm{R}_{\mathrm{T}}| | 300 \Omega=50 \Omega$. The closest standard $1 \%$ value for $\mathrm{R}_{\mathrm{T}}$ is $60.4 \Omega$.

Figure 47. Adding Termination Resistor $R_{T}$
3. Figure 47 shows that the effective $\mathrm{R}_{\mathrm{G}}$ in the upper feedback loop is now greater than the $\mathrm{R}_{\mathrm{G}}$ in the lower loop due to the addition of the termination resistors. To compensate for the imbalance of the gain resistors, a correction resistor ( $\mathrm{R}_{T \mathrm{~S}}$ ) is added in series with $\mathrm{R}_{\mathrm{G}}$ in the lower loop. $\mathrm{R}_{\mathrm{TS}}$ is equal to the Thevenin equivalent of the source resistance $\mathrm{R}_{s}$ and the termination resistance $\mathrm{R}_{\mathrm{T}}$ and is equal to $\mathrm{R}_{s} \| \mathrm{R}_{\mathrm{T}}$.

Figure 48. Calculating the Thevenin Equivalent
$\mathrm{R}_{\mathrm{TS}}=\mathrm{R}_{\mathrm{TH}}=\mathrm{R}_{S} \| \mathrm{R}_{\mathrm{T}}=27.4 \Omega$. Note that $\mathrm{V}_{\mathrm{TH}}$ is greater than 1 V p-p, which was obtained with $\mathrm{R}_{\mathrm{T}}=50 \Omega$. The modified circuit with the Thevenin equivalent of the terminated source and $\mathrm{R}_{\mathrm{TS}}$ in the lower feedback loop is shown in Figure 49.

Figure 49. Thevenin Equivalent and Matched Gain Resistors
Figure 49 presents a tractable circuit with matched feedback loops that can be easily evaluated.

It is useful to point out two effects that occur with a terminated input. The first is that the value of $\mathrm{R}_{\mathrm{G}}$ is increased in both loops, lowering the overall closed-loop gain. The second is that $\mathrm{V}_{\mathrm{TH}}$ is a little larger than $1 \mathrm{~V} \mathrm{p}-\mathrm{p}$, as it would be if $R_{T}=50 \Omega$. These two effects have opposite impacts on the output voltage, and for large resistor values in the feedback loops ( $\sim 1 \mathrm{k} \Omega$ ), the effects essentially cancel each other out. For small $R_{F}$ and $R_{G}$, however, the diminished closed-loop gain is not canceled completely by the increased $\mathrm{V}_{\text {тн }}$. This can be seen by evaluating Figure 49.

The desired differential output in this example is 2 V p-p because the terminated input signal was 1 V p-p and the closed-loop gain $=2$. The actual differential output voltage, however, is equal to $(1.09 \mathrm{~V} \mathrm{p}-\mathrm{p})(400 / 227.4)=1.92 \mathrm{~V} p-\mathrm{p}$. To obtain the desired output voltage of 2 V p-p, a final gain adjustment can be made by increasing $\mathrm{R}_{\mathrm{F}}$ without modifying any of the input circuitry (see Step 4).
4. The feedback resistor value is modified as a final gain adjustment to obtain the desired output voltage.
To make the output voltage Vout $=2 \mathrm{~V} p-\mathrm{p}$, calculate $\mathrm{R}_{\mathrm{F}}$ by

$$
R_{F}=
$$

$$
\frac{\left(\text { Desired } V_{\text {OUT }, d m}\right)\left(R_{G}+R_{T S}\right)}{V_{T H}}=\frac{\left(2 V_{P-P}\right)(227.4 \Omega)}{1.09 V_{P-P}}=417 \Omega
$$

The closest standard $1 \%$ values to $417 \Omega$ are $412 \Omega$ and $422 \Omega$. Choosing $422 \Omega$ gives a differential output voltage of 2.02 V p-p.
The final circuit is shown in Figure 50.

Figure 50. Terminated Single-Ended-to-Differential System with $G=2$

## INPUT COMMON-MODE VOLTAGE RANGE

The ADA4939-1/ADA4939-2 input common-mode range is centered between the two supply rails, in contrast to other ADC drivers with level-shifted input ranges, such as the ADA4937-1/ ADA4937-2. The centered input common-mode range is best suited to ac-coupled, differential-to-differential and dual supply applications.

For 5 V single-supply operation, the input common-mode range at the summing nodes of the amplifier is specified as 1.1 V to 3.9 V and is specified as 0.9 V to 2.4 V with a 3.3 V supply. To avoid nonlinearities, the voltage swing at the +IN and -IN terminals must be confined to these ranges.

## INPUT AND OUTPUT CAPACITIVE AC COUPLING

Input ac coupling capacitors can be inserted between the source and $\mathrm{R}_{\mathrm{G}}$. This ac coupling blocks the flow of the dc commonmode feedback current and causes the ADA4939-1/ADA4939-2 dc input common-mode voltage to equal the dc output commonmode voltage. These ac coupling capacitors must be placed in both loops to keep the feedback factors matched.
Output ac coupling capacitors can be placed in series between each output and its respective load. See Figure 54 for an example that uses input and output capacitive ac coupling.

## MINIMUM R ${ }_{\mathrm{G}}$ VALUE OF 50 ת

Due to the wide bandwidth of the ADA4939-1/ADA4939-2, the value of $\mathrm{R}_{\mathrm{G}}$ must be greater than or equal to $50 \Omega$ to provide sufficient damping in the amplifier front end. In the terminated case, $\mathrm{R}_{\mathrm{G}}$ includes the Thevenin resistance of the source and load terminations.

## SETTING THE OUTPUT COMMON-MODE VOLTAGE

The Vосм/Vосмх pin of the $^{\text {ADA }}$ 4939-1/ADA4939-2 is internally biased with a voltage divider comprising two $20 \mathrm{k} \Omega$ resistors at a voltage approximately equal to the midsupply point, $\left[\left(+\mathrm{V}_{\mathrm{s}}\right)+\right.$ $\left.\left(-\mathrm{V}_{\mathrm{S}}\right)\right] / 2$. Because of this internal divider, the $\mathrm{V}_{\text {осм }} / \mathrm{V}_{\text {оСмх }}$ pin sources and sinks current, depending on the externally applied voltage and its associated source resistance. Relying on the internal bias results in an output common-mode voltage that is within about 100 mV of the expected value.
In cases where more accurate control of the output commonmode level is required, it is recommended that an external source or resistor divider be used with source resistance less than $100 \Omega$. The output common-mode offset listed in the Specifications section assumes that the $V_{\text {OCM }}$ input is driven by a low impedance voltage source.

It is also possible to connect the Vocm input to a common-mode level (CML) output of an ADC. However, care must be taken to ensure that the output has sufficient drive capability. The input impedance of the $V_{\text {осм }} / V_{\text {осмх }}$ pin is approximately $10 \mathrm{k} \Omega$. If multiple ADA4939-1/ADA4939-2 devices share one reference output, it is recommended that a buffer be used.

## ADA4939-1/ADA4939-2

## LAYOUT, GROUNDING, AND BYPASSING

As a high speed device, the ADA4939-1 is sensitive to the PCB environment in which it operates. Realizing its superior performance requires attention to the details of high speed PCB design. This section shows a detailed example of how the ADA4939-1 was addressed.

The first requirement is a solid ground plane that covers as much of the board area around the ADA4939-1 as possible. However, the area near the feedback resistors ( $\mathrm{R}_{\mathrm{F}}$ ), gain resistors $\left(\mathrm{R}_{\mathrm{G}}\right)$, and the input summing nodes (Pin 2 and Pin 3) must be cleared of all ground and power planes (see Figure 51). Clearing the ground and power planes minimizes any stray capacitance at these nodes and prevents peaking of the response of the amplifier at high frequencies.

The thermal resistance, $\theta_{\mathrm{JA}}$, is specified for the device, including the exposed pad, soldered to a high thermal conductivity four-layer circuit board, as described in EIA/JESD 51-7.

Bypass the power supply pins as close to the device as possible and directly to a nearby ground plane. Use high frequency ceramic chip capacitors. It is recommended to use two parallel bypass capacitors ( 1000 pF and $0.1 \mu \mathrm{~F}$ ) for each supply. Place the 1000 pF capacitor closer to the device. Further away, provide low frequency bypassing, using $10 \mu \mathrm{~F}$ tantalum capacitors from each supply to ground.
Ensure that signal routing is short and direct to avoid parasitic effects. Wherever complementary signals exist, provide a symmetrical layout to maximize balanced performance. When routing differential signals over a long distance, ensure that the PCB traces are close together, and twist any differential wiring such that the loop area is minimized which reduces radiated energy and makes the circuit less susceptible to interference.

## HIGH PERFORMANCE ADC DRIVING

The ADA4939-1/ADA4939-2 are ideally suited for broadband ac-coupled and differential-to-differential applications on a single supply.
The circuit in Figure 54 shows a front-end connection for an ADA4939-1 driving an AD9445, 14-bit, 105 MSPS ADC, with ac coupling on the ADA4939-1 input and output. (The AD9445 achieves its optimum performance when driven differentially.) The ADA4939-1 eliminates the need for a transformer to drive the ADC and perform a single-ended-to-differential conversion and buffering of the driving signal.

The ADA4939-1 is configured with a single 5 V supply and gain of 2 for a single-ended input to differential output. The $60.4 \Omega$ termination resistor, in parallel with the single-ended input impedance of approximately $300 \Omega$, provides a $50 \Omega$ termination for the source. The additional $27.4 \Omega$ (227.4 $\Omega$ total) at the inverting input balances the parallel impedance of the $50 \Omega$ source and the termination resistor driving the noninverting input.

In this example, the signal generator has a 1 V p-p symmetric, ground-referenced bipolar output when terminated in $50 \Omega$.

The Vосм pin of the ADA4939-1 is bypassed for noise reduction and left floating such that the internal divider sets the output common-mode voltage nominally at midsupply. Because the inputs are ac-coupled, no dc common-mode current flows in the feedback loops, and a nominal dc level of midsupply is present at the amplifier input terminals. Besides placing the amplifier inputs at their optimum levels, the ac coupling technique lightens the load on the amplifier and dissipates less power than applications with dc-coupled inputs. With an output commonmode voltage of nominally 2.5 V , each ADA4939-1 output swings between 2.0 V and 3.0 V , providing a gain of 2 and a 2 V p-p differential signal to the ADC input.

The output of the amplifier is ac-coupled to the ADC through a second-order, low-pass filter with a cutoff frequency of 100 MHz . This reduces the noise bandwidth of the amplifier and isolates the driver outputs from the ADC inputs.
The AD9445 is configured for a 2 V p-p full-scale input by connecting the SENSE pin to AGND, as shown in Figure 54.
