

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

ADM1024

System Hardware Monitor with Remote Diode Thermal Sensing

The ADM1024 is a complete system hardware monitor for microprocessor-based systems, providing measurement and limit comparison of various system parameters. Eight measurement inputs are provided; three are dedicated to monitoring 5.0 V and 12 V power supplies and the processor core voltage. The ADM1024 can monitor a fourth power supply voltage by measuring its own V_{CC} . One input (two pins) is dedicated to a remote temperature-sensing diode. Two more pins can be configured as inputs to monitor a 2.5 V supply and a second processor core voltage, or as a second temperature-sensing input. The remaining two inputs can be programmed as general purpose analog inputs or as digital fan speed measuring inputs. Measured values can be read out via a serial System Management Bus and values for limit comparisons can be programmed in over the same serial bus. The high speed successive approximation ADC allows frequent sampling of all analog channels to ensure a fast interrupt response to any out-of-limit measurement.

The ADM1024's 2.8 V to 5.5 V supply voltage range, low supply current, and SMBus interface make it ideal for a wide range of applications. These include hardware monitoring and protection applications in personal computers, electronic test equipment, and office electronics.

Features

- Up to Nine Measurement Channels
- Inputs Programmable-to-Measure Analog Voltage, Fan Speed or External Temperature
- External Temperature Measurement with Remote Diode (Two Channels)
- On-chip Temperature Sensor
- Five Digital Inputs for VID Bits
- LDCM Support
- System Management Bus (SMBus)
- Chassis Intrusion Detect
- Interrupt and Overtemperature Outputs
- Programmable $\overline{\text{RESET}}$ Input Pin
- Shutdown Mode to Minimize Power Consumption
- Limit Comparison of All Monitored Values
- This is a Pb-Free Device*

Applications

- Network Servers and Personal Computers
- Microprocessor-Based Office Equipment
- Test Equipment and Measuring Instruments

*For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

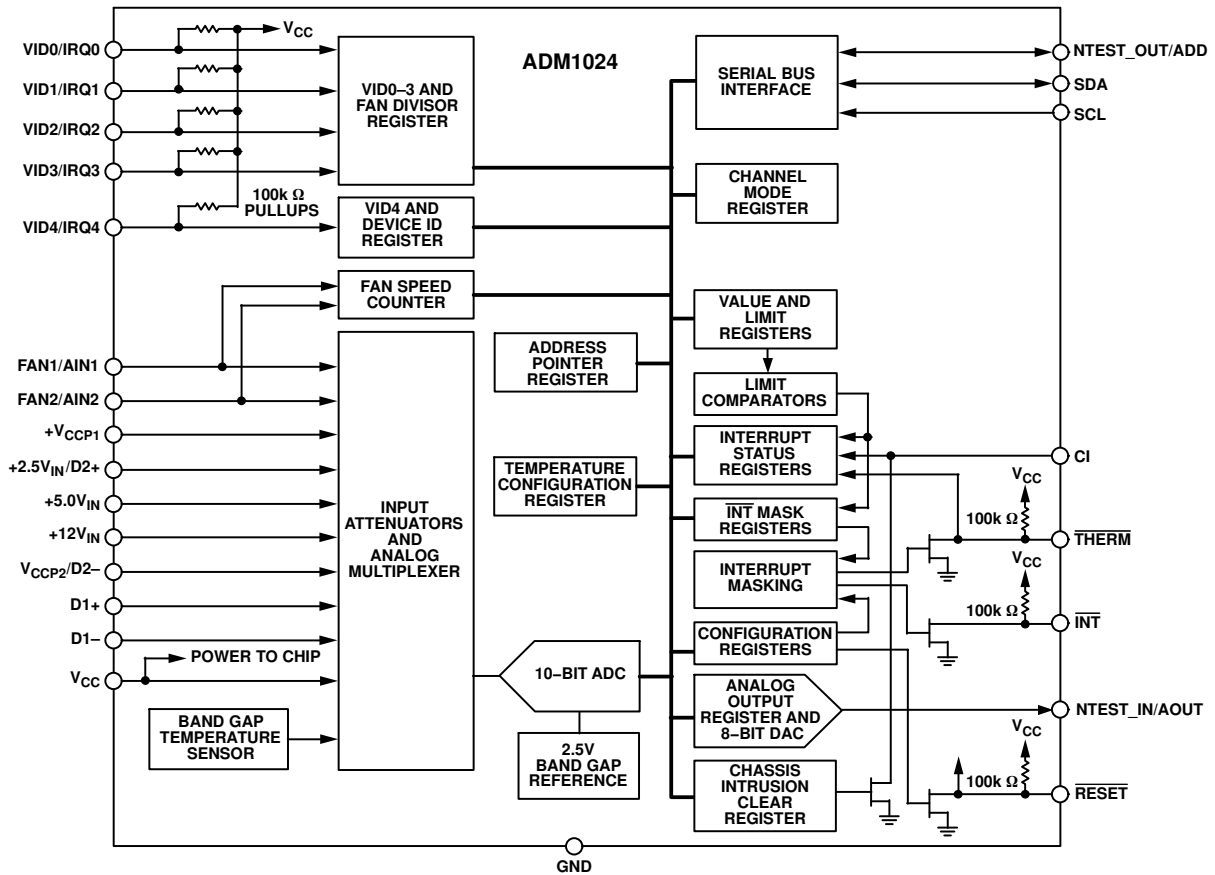

Figure 1. Functional Block Diagram

Table 1. ABSOLUTE MAXIMUM RATINGS

Parameter	Rating	Unit
Positive Supply Voltage (V_{CC})	6.5	V
Voltage on 12 V_{IN} Pin	20	V
Voltage on AOUT, NTEST_OUT ADD, 2.5 $V_{IN}/D2+$	-0.3 to ($V_{CC} + 0.3$)	V
Voltage on Any Other Input or Output Pin	-0.3 to +6.5	V
Input Current at Any Pin	± 5	mA
Package Input Current	± 20	mA
Maximum Junction Temperature (T_{JMAX})	150	$^{\circ}C$
Storage Temperature Range	-65 to +150	$^{\circ}C$
Lead Temperature, Soldering Reflow Temperature	260	$^{\circ}C$
ESD Rating All Pins	2000	V

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

NOTE: This device is ESD sensitive. Use standard ESD precautions when handling.

ADM1024

Table 3. PIN ASSIGNMENT

Pin No.	Mnemonic	Description
1	NTEST_OUT/ADD	Digital I/O. Dual function pin. This is a three-state input that controls the two LSBs of the Serial Bus Address. This pin functions as an output when doing a NAND test.
2	THERM	Digital I/O. Dual function pin. This pin functions as an interrupt output for temperature interrupts only, or as an interrupt input for fan control. It has an on-chip 100 k Ω pullup resistor.
3	SDA	Digital I/O. Serial bus bidirectional data. Open-drain output.
4	SCL	Digital Input. Serial bus clock.
5	FAN1/AIN1	Programmable Analog/Digital Input. 0 V to 2.5 V analog input or digital (0 to V _{CC}) amplitude fan tachometer input.
6	FAN2/AIN2	Programmable Analog/Digital Input. 0 V to 2.5 V analog input or digital (0 to V _{CC}) amplitude fan tachometer input.
7	CI	Digital I/O. An active high input from an external latch that captures a Chassis Intrusion event. This line can go high without any clamping action, regardless of the powered state of the ADM1024. The ADM1024 provides an internal open drain on this line, controlled by Bit 6 of Register 40h or Bit 7 of Register 46h, to provide a minimum 20 ms pulse on this line to reset the external Chassis Intrusion Latch.
8	GND	System Ground.
9	V _{CC}	Power (2.8 V to 5.5 V). Typically powered from 3.3 V power rail. Bypass with the parallel combination of 10 μ F (electrolytic or tantalum) and 0.1 μ F (ceramic) bypass capacitors.
10	INT	Digital Output. Interrupt request (open-drain). The output is enabled when Bit 1 of Register 40h is set to 1. The default state is disabled. It has an on-chip 100 k Ω pullup resistor.
11	NTEST_IN/AOUT	Digital Input/Analog Output. An active-high input that enables NAND Test mode board-level connectivity testing. Refer to the section on NAND testing. Also functions as a programmable analog output when NAND Test is not selected.
12	RESET	Digital I/O. Master Reset, 5 mA driver (open drain), active low output with a 45 ms minimum pulse width. Set using Bit 4 in Register 40h. Also acts as reset input when pulled low (e.g., power-on reset). It has an on-chip 100 k Ω pullup resistor.
13	D1-	Analog Input. Connected to cathode of first external temperature-sensing diode.
14	D1+	Analog Input. Connected to anode of first external temperature-sensing diode.
15	+12 V _{IN}	Programmable Analog Input. Monitors 12 V supply.
16	+5.0 V _{IN}	Analog Input. Monitors 5.0 V supply.
17	V _{CCP2} /D2-	Programmable Analog Input. Monitors second processor core voltage or cathode of second external temperature-sensing diode.
18	+2.5 V _{IN} /D2+	Programmable Analog Input. Monitors 2.5 V supply or anode of second external temperature-sensing diode.
19	+V _{CCP1}	Analog Input. Monitors first processor core voltage (0 V to 3.6 V).
20	VID4/IRQ4	Digital Input. Core Voltage ID readouts from the processor. This value is read into the VID4 Status Register. Can also be reconfigured as an interrupt input. It has an on-chip 100 k Ω pullup resistor.
21	VID3/IRQ3	Digital Input. Core Voltage ID readouts from the processor. This value is read into the VID0-VID3 Status Register. Can also be reconfigured as an interrupt input. It has an on-chip 100 k Ω pullup resistor.
22	VID2/IRQ2	Digital Input. Core Voltage ID readouts from the processor. This value is read into the VID0-VID3 Status Register. Can also be reconfigured as an interrupt input. It has an on-chip 100 k Ω pullup resistor.
23	VID1/IRQ1	Digital Input. Core Voltage ID readouts from the processor. This value is read into the VID0-VID3 Status Register. Can also be reconfigured as an interrupt input. It has an on-chip 100 k Ω pullup resistor.
24	VID0/IRQ0	Digital Input. Core Voltage ID readouts from the processor. This value is read into the VID0-VID3 Status Register. Can also be reconfigured as an interrupt input. It has an on-chip 100 k Ω pullup resistor.

- All voltages are measured with respect to GND, unless otherwise specified.
- Typicals are at $T_A = 25^\circ\text{C}$ and represent the most likely parametric norm. Shutdown current typ is measured with $V_{CC} = 3.3$ V.
- TUE (Total Unadjusted Error) includes Offset, Gain, and Linearity errors of the ADC, multiplexer, and on-chip input attenuators, including an external series input protection resistor value between 0 k Ω and 1 k Ω .
- Total monitoring cycle time is nominally $m \times 755 \mu\text{s} + n \times 33244 \mu\text{s}$, where m is the number of channels configured as analog inputs, plus 2 for the internal V_{CC} measurement and internal temperature sensor, and n is the number of channels configured as external temperature channels (D1 and D2).
- The total fan count is based on two pulses per revolution of the fan tachometer output.
- Open-drain digital outputs may have an external pullup resistor connected to a voltage lower or higher than V_{CC} (up to 6.5 V absolute maximum).
- All logic inputs except ADD are tolerant of 5.0 V logic levels, even if V_{CC} is less than 5.0 V. ADD is a three-state input that may be connected to V_{CC} , GND, or left open-circuit.
- Timing specifications are tested at logic levels of $V_{IL} = 0.8$ V for a falling edge and $V_{IH} = 2.2$ V for a rising edge.

ADM1024

General Description

The ADM1024 is a complete system hardware monitor for microprocessor-based systems. The device communicates with the system via a serial SMBus. The serial bus controller has a hardwired address line for device selection (Pin 1), a serial data line for reading and writing addresses and data (SDA, Pin 14), and an input line for the serial clock (Pin 3), and an input line for the serial clock (Pin 4). All control and programming functions of the ADM1024 are performed over the serial bus.

Measurement Inputs

Programmability of the measurement inputs makes the ADM1024 extremely flexible and versatile. The device has a 10-bit ADC and nine measurement input pins that can be configured in different ways.

Pins 5 and 6 can be programmed as general-purpose analog inputs with a range of 0 V to 2.5 V, or as digital inputs to monitor the speed of fans with digital tachometer outputs. The fan inputs can be programmed to accommodate fans with different speeds and different numbers of pulses per revolution from their tachometer outputs.

Pins 13 and 14 are dedicated temperature inputs and may be connected to the cathode and anode of an external temperature sensing diode.

Pins 15, 16, and 19 are dedicated analog inputs with on-chip attenuators, configured to monitor 12 V, 5.0 V, and the processor core voltage, respectively.

Pins 17 and 18 may be configured as analog inputs with on-chip attenuators to monitor a second processor core voltage and a 2.5 V supply, or they may be configured as a temperature input and connected to a second temperature-sensing diode.

The ADC also accepts input from an on-chip band gap temperature sensor that monitors system-ambient temperature.

Finally, the ADM1024 monitors the supply from which it is powered, so there is no need for a separate 3.3 V analog input if the chip V_{CC} is 3.3 V. The range of this V_{CC} measurement can be configured for either a 3.3 V or 5.0 V V_{CC} by Bit 3 of the Channel Mode Register.

Sequential Measurement

When the ADM1024 monitoring sequence is started, it cycles sequentially through the measurement of analog inputs and the temperature sensor, while at the same time the fan speed inputs are independently monitored. Measured values from these inputs are stored in Value Registers. These can be read out over the serial bus, or can be compared with programmed limits stored in the Limit Registers. The results of out-of-limit comparisons are stored in the Interrupt Status Registers, and will generate an interrupt on the \overline{INT} line (Pin 10).

Any or all of the Interrupt Status Bits can be masked by appropriate programming of the Interrupt Mask Register.

Processor Voltage ID

Five digital inputs (VID4 to VID0—Pins 20 to 24) read the processor voltage ID code. These inputs can also be reconfigured as interrupt inputs.

The VID pins have internal 100 k Ω pullup resistors.

Chassis Intrusion

A chassis intrusion input (Pin 7) is provided to detect unauthorized tampering with the equipment.

RESET

A \overline{RESET} input/output (Pin 12) is provided. Pulling this pin low will reset all ADM1024 internal registers to default values. The ADM1024 can also be programmed to give a low going 45 ms reset pulse at this pin.

Analog Output

The ADM1024 contains an on-chip, 8-bit DAC with an output range of 0 V to 2.5 V (Pin 11). This is typically used to implement a temperature-controlled fan by controlling the speed of a fan dependent upon the temperature measured by the on-chip temperature sensor.

Testing of board level connectivity is simplified by providing a NAND tree test function. The AOUT (Pin 11) also doubles as a NAND test input, while Pin 1 doubles as a NAND tree output.

Internal Registers of the ADM1024

A brief description of the ADM1024's principal internal registers follows. More detailed information on the function of each register is given in Table 10 to Table 23:

- Configuration Registers: Provide control and configuration.
- Channel Mode Register: Stores the data for the operating modes of the input channels.
- Address Pointer Register: This register contains the address that selects one of the other internal registers. When writing to the ADM1024, the first byte of data is always a register address, which is written to the Address Pointer Register.
- Interrupt (\overline{INT}) Status Registers: Two registers to provide status of each interrupt event. These registers are also mirrored at addresses 4Ch and 4Dh.
- Interrupt (\overline{INT}) Mask Registers: Allow masking of individual interrupt sources.
- Temperature Configuration Register: The configuration of the temperature interrupt is controlled by the lower three bits of this register.
- VID/Fan Divisor Register: The status of the VID0 to VID4 pins of the processor can be written to and read from these registers. Divisor values for fan speed measurement are also stored in this register.

- Value and Limit Registers: The results of analog voltage inputs, temperature, and fan speed measurements are stored in these registers, along with their limit values.
- Analog Output Register: The code controlling the analog output DAC is stored in this register.
- Chassis Intrusion Clear Register: A signal latched on the chassis intrusion pin can be cleared by writing to this register.

Serial Bus Interface

Control of the ADM1024 is carried out via the serial bus. The ADM1024 is connected to this bus as a slave device, under the control of a master device, e.g., ICH.

The ADM1024 has a 7-bit serial bus address. When the device is powered up, it will do so with a default serial bus address. The 5 MSBs of the address are set to 01011, and the 2 LSBs are determined by the logical states of Pin 1 (NTEST OUT/ADD). This is a three-state input that can be grounded, connected to V_{CC}, or left open-circuit to give three different addresses.

Table 5. ADD PIN TRUTH TABLE

ADD Pin	A1	A0
GND	1	0
No Connect	0	0
V _{CC}	0	1

If ADD is left open-circuit, the default address will be 0101100. ADD is sampled only at powerup, so any changes made while power is on will have no immediate effect.

The facility to make hardwired changes to A1 and A0 allows the user to avoid conflicts with other devices sharing the same serial bus, for example, if more than one ADM1024 is used in a system.

The serial bus protocol operates as follows:

1. The master initiates data transfer by establishing a START condition, defined as a high-to-low transition on the serial data line SDA while the serial clock line, SCL, remains high. This indicates that an address/data stream will follow. All slave peripherals connected to the serial bus respond to the START condition, and shift in the next eight bits, consisting of a 7-bit address (MSB first) plus an R/W bit, which determines the direction of the data transfer, i.e., whether data will be written to or read from the slave device.

The peripheral whose address corresponds to the transmitted address responds by pulling the data line low during the low period before the ninth clock pulse, known as the Acknowledge Bit. All other devices on the bus now remain idle while the selected device waits for data to be read from or written to it. If the R/W bit is a 0, the master will write to the slave device. If the R/W bit is a 1, the master will read from the slave device.

2. Data is sent over the serial bus in sequences of nine clock pulses, eight bits of data followed by an Acknowledge Bit from the slave device. Transitions on the data line must occur during the low period of the clock signal and remain stable during the high period, as a low-to-high transition when the clock is high may be interpreted as a STOP signal. The number of data bytes that can be transmitted over the serial bus in a single Read or Write operation is limited only by what the master and slave devices can handle.
3. When all data bytes have been read or written, stop conditions are established. In Write mode, the master will pull the data line high during the tenth clock pulse to assert a STOP condition. In Read mode, the master device will override the Acknowledge Bit by pulling the data line high during the low period before the ninth clock pulse. This is known as No Acknowledge. The master will then take the data line low during the low period before the tenth clock pulse, then high during the tenth clock pulse to assert a STOP condition.

Any number of bytes of data may be transferred over the serial bus in one operation, but it is not possible to mix read and write in one operation because the type of operation is determined at the beginning and cannot subsequently be changed without starting a new operation.

In the case of the ADM1024, write operations contain either one or two bytes, and read operations contain one byte and perform the following functions.

To write data to one of the device data registers or read data from it, the Address Pointer Register must be set so that the correct data register is addressed, then data can be written into that register or read from it. The first byte of a write operation always contains an address that is stored in the Address Pointer Register. If data is to be written to the device, the write operation contains a second data byte that is written to the register selected by the Address Pointer Register. This is illustrated in Figure 10 The device address is sent over the bus followed by R/W set to 0. This is followed by two data bytes. The first data byte is the address of the internal data register to be written to, which is stored in the Address Pointer Register. The second data byte is the data to be written to the internal data register.

When reading data from a register, there are two possibilities:

1. If the ADM1024's Address Pointer Register value is unknown or not the desired value, it is first necessary to set it to the correct value before data can be read from the desired data register. This is done by performing a write to the ADM1024 as before, but only the data byte containing the register address is sent, as data is not to be written to the register. This is shown in Figure 11. A read operation is then performed consisting of

ADM1024

the serial bus address, R/\overline{W} bit set to 1, followed by the data byte read from the data register. This is shown in Figure 12.

2. If the Address Pointer Register is known to be already at the desired address, data can be read

from the corresponding data register without first writing to the Address Pointer Register, so Figure 11 can be omitted.

Figure 10. Writing a Register Address to the Address Pointer Register, then Writing Data to the Selected Register

Figure 11. Writing to the Address Pointer Register Only

Figure 12. Reading Data from a Previously Selected Register

NOTES

1. Although it is possible to read a data byte from a data register without first writing to the Address Pointer Register, if the Address Pointer Register is already at the correct value, it is not possible to write data to a register without writing to the Address Pointer Register because the first data byte of a write is always written to the Address Pointer Register.

2. In Figure 10 to Figure 12, the serial bus address is shown as the default value 01011(A1)(A0), where A1 and A0 are set by the three-state ADD pin.

Measurement Inputs

The ADM1024 has nine external measurement pins that can be configured to perform various functions by programming the Channel Mode Register.

ADM1024

Pins 13 and 14 are dedicated to temperature measurement, while Pins 15, 16, and 19 are dedicated analog input channels. Their function is unaffected by the Channel Mode Register.

Pins 5 and 6 can be individually programmed as analog inputs, or as digital fan speed measurement inputs, by programming Bits 0 and 1 of the Channel Mode Register.

Bit 3 of the Channel Mode Register configures the internal V_{CC} measurement range for either 3.3 V or 5.0 V.

Bits 4 to 6 of the Channel Mode Register enable or disable Pins 22 to 24 when they are configured as interrupt inputs by setting Bit 7 of the Channel Mode Register. This function is controlled for Pins 20 and 21 by Bits 6 and 7 of Configuration Register 2.

Pins 17 and 18 can be configured as analog inputs or as inputs for external temperature-sensing diodes by programming Bit 2 of the Channel Mode Register.

A truth table for the Channel Mode Register is given in Table 6.

Table 6. CHANNEL MODE REGISTER (Note 1)

Channel Mode Register Bit	Controls Pin(s)	Function
0	5	0 = FAN1, 1 = A_{IN1}
1	6	0 = FAN2, 1 = A_{IN2}
2	17, 18	0 = 2.5 V, V_{CCP2} , 1 = D2-, D2+
3	Int. V_{CC} Meas.	0 = 3.3 V, 1 = 5.0 V

A-to-D Converter

These inputs are multiplexed into the on-chip, successive approximation, Analog-to-Digital Converter (ADC). This has a resolution of eight bits. The basic input range is 0 V to 2.5 V, which is the input range of AIN1 and AIN2, but five of the inputs have built-in attenuators to allow measurement of 2.5 V, 5.0 V, 12 V, and the processor core voltages V_{CCP1} and V_{CCP2} without any external components. To allow for the tolerance of these supply voltages, the ADC produces an output of 3/4 full scale (decimal 192) for the nominal input voltage, and so has adequate headroom to cope with overvoltages. Table 7 shows the input ranges of the analog inputs and output codes of the ADC.

When the ADC is running, it samples and converts an input every 748 μs, except for the external temperature (D1 and D2) inputs. These have special input signal conditioning and are averaged over 16 conversions to reduce noise, and a measurement on one of these inputs takes nominally 9.6 ms.

Input Circuits

The internal structure for the analog inputs is shown in Figure 13. Each input circuit consists of an input protection diode, an attenuator, plus a capacitor to form a first-order low-pass filter that gives the input immunity to high frequency noise.

Figure 13. Structure of Analog Inputs

2.5 V Input Precautions

When using the 2.5 V input, the following precautions should be noted. There is a parasitic diode between Pin 18 and V_{CC} due to the presence of a PMOS current source (which is used when Pin 18 is configured as a temperature input). This will become forward biased if Pin 18 is more than 0.3 V above V_{CC}. Therefore, V_{CC} should never be powered off with a 2.5 V input connected.

Setting Other Input Ranges

A_{IN1} and A_{IN2} can easily be scaled to voltages other than 2.5 V. If the input voltage range is zero to some positive voltage, all that is required is an input attenuator, as shown in Figure 14.

Figure 14. Scaling A_{IN(1-2)}

Negative and bipolar input ranges can be accommodated by using a positive reference voltage to offset the input voltage range so it is always positive.

$$\frac{R1}{R2} = \frac{(V_{fs} - 2.5)}{2.5} \quad (\text{eq. 1})$$

To measure a negative input voltage, an attenuator can be used as shown in Figure 15.

Figure 15. Scaling and Offsetting A_{IN(1-2)} for Negative Inputs

This is a simple and cheap solution, but the following point should be noted. Since the input signal is offset but not inverted, the input range is transposed. An increase in the magnitude of the -12 V supply (going more negative) will cause the input voltage to fall and give a lower output code from the ADC. Conversely, a decrease in the magnitude of the -12 V supply will cause the ADC code to increase. The maximum negative voltage corresponds to zero output from the ADC. This means that the upper and lower limits will be transposed.

$$\frac{R1}{R2} = \left| \frac{V_{fs} -}{V_{OS}} \right| \quad (\text{eq. 2})$$

Bipolar input ranges can easily be accommodated. By making R1 equal to R2 and V_{OS} = 2.5 V, the input range is ±2.5 V. Other input ranges can be accommodated by adding a third resistor to set the positive full-scale input voltage.

Figure 16. Scaling and Offsetting A_{IN(1-2)} for Bipolar Inputs

(R3 has no effect as the input voltage at the device pin is zero when V_{IN} = minus full scale.)

$$\frac{R1}{R2} = \frac{|V_{fs} - |}{R2} \quad (\text{eq. 3})$$

(R2 has no effect as the input voltage at the device pin is 2.5 V when V_{IN} = plus full scale).

$$\frac{R1}{R3} = \frac{(V_{fs+} - 2.5)}{2.5} \quad (\text{eq. 4})$$

Offset voltages other than 2.5 V can be used, but the calculation becomes more complicated.

Temperature Measurement System

Local Temperature Measurement

The ADM1024 contains an on-chip band gap temperature sensor, whose output is digitized by the on-chip ADC. The temperature data is stored in the Temperature Value Register (address 27h) and the LSB from Bits 6 and 7 of the Temperature Configuration Register (address 4Bh). As both positive and negative temperatures can be measured, the temperature data is stored in twos complement format, as shown in Table 8. Theoretically, the temperature sensor and ADC can measure temperatures from -128°C to $+127^{\circ}\text{C}$ with a resolution of 1°C , although temperatures below -40°C and above $+125^{\circ}\text{C}$ are outside the operating temperature range of the device.

External Temperature Measurement

The ADM1024 can measure the temperature of two external diode sensors or diode-connected transistors, connected to Pins 13 and 14 or 17 and 18.

Pins 13 and 14 are a dedicated temperature input channel. Pins 17 and 18 can be configured to measure a diode sensor by setting Bit 2 of the Channel Mode Register to 1.

The forward voltage of a diode or diode-connected transistor, operated at a constant current, exhibits a negative temperature coefficient of about $-2 \text{ mV}/^{\circ}\text{C}$. Unfortunately, the absolute value of V_{BE} varies from device to device, and individual calibration is required to null this out, so the technique is unsuitable for mass production.

The technique used in the ADM1024 is to measure the change in V_{BE} when the device is operated at two different currents.

This is given by:

$$\Delta V_{be} = \frac{KT}{q} \times \ln(N) \quad (\text{eq. 5})$$

where:

K is Boltzmann's constant.

q is the charge on the carrier.

T is the absolute temperature in Kelvins.

N is the ratio of the two currents.

Figure 17 shows the input signal conditioning used to measure the output of an external temperature sensor. This figure shows the external sensor as a substrate transistor provided for temperature monitoring on some microprocessors, but it could equally well be a discrete transistor.

Figure 17. Signal Conditioning for External Diode Temperature Sensors

If a discrete transistor is used, the collector will not be grounded and should be linked to the base. If a PNP transistor is used, the base is connected to the D- input and the emitter to the D+ input. If an NPN transistor is used, the emitter is connected to the D- input and the base to the D+ input.

To prevent ground noise from interfering with the measurement, the more negative terminal of the sensor is not referenced to ground, but is biased above ground by an internal diode at the D- input. As the sensor is operating in a noisy environment, C1 is provided as a noise filter. See the Layout Considerations section for more information on C1.

To measure ΔV_{BE} , the sensor is switched between operating currents of I and $N \times I$. The resulting waveform is passed through a 65 kHz low-pass filter to remove noise, then to a chopper-stabilized amplifier that performs the functions of amplification and rectification of the waveform to produce a dc voltage proportional to ΔV_{BE} . This voltage is measured by the ADC to give a temperature output in 8-bit twos complement format. To further reduce the effects of noise, digital filtering is performed by averaging the results of 16 measurement cycles. An external temperature measurement takes nominally 9.6 ms.

The results of external temperature measurements are stored in 8-bit, twos complement format, as illustrated in Table 8.

Table 8. TEMPERATURE DATA FORMAT

+100°C	0110 0100
+125°C	0111 1101
+127°C	0111 1111

Layout Considerations

Digital boards can be electrically noisy environments, and care must be taken to protect the analog inputs from noise, particularly when measuring the very small voltages from a remote diode sensor. The following precautions should be taken:

1. Place the ADM1024 as close as possible to the remote sensing diode. Provided that the worst noise sources such as clock generators, data/address buses, and CRTs are avoided, this distance can be 4 inches to 8 inches.
2. Route the D+ and D- tracks close together, in parallel, with grounded guard tracks on each side. Provide a ground plane under the tracks if possible.
3. Use wide tracks to minimize inductance and reduce noise pickup. A 10 mil track minimum width and spacing is recommended.

Figure 18. Arrangement of Signal Tracks

4. Try to minimize the number of copper/solder joints, which can cause thermocouple effects. Where copper/solder joints are used, make sure that they are in both the D+ and D- path and at the same temperature. Thermocouple effects should not be a major problem as 1°C corresponds to about 240 μV,

and thermocouple voltages are about 3 μV/°C of temperature difference. Unless there are two thermocouples with a big temperature differential between them, thermocouple voltages should be much less than 200 mV.

5. Place 0.1 μF bypass and 2200 pF input filter capacitors close to the ADM1024.
6. If the distance to the remote sensor is more than 8 inches, the use of twisted pair cable is recommended. This will work up to about 6 feet to 12 feet.
7. For really long distances (up to 100 feet) use shielded twisted pair such as Belden #8451 microphone cable. Connect the twisted pair to D+ and D- and the shield to GND close to the ADM1024. Leave the remote end of the shield unconnected to avoid ground loops.

Because the measurement technique uses switched current sources, excessive cable and/or filter capacitance can affect the measurement. When using long cables, the filter capacitor may be reduced or removed.

Cable resistance can also introduce errors. A 1 Ω series resistance introduces about 0.5°C error.

Limit Values

Limit values for analog measurements are stored in the appropriate limit registers. In the case of voltage measurements, high and low limits can be stored so that an interrupt request will be generated if the measured value goes above or below acceptable values. In the case of temperature, a Hot Temperature or High Limit can be programmed, and a Hot Temperature Hysteresis or Low Limit, which will usually be some degrees lower. This can be useful as it allows the system to be shut down when the hot limit is exceeded, and restarted automatically when it has cooled down to a safe temperature.

Monitoring Cycle Time

The monitoring cycle begins when a 1 is written to the Start Bit (Bit 0), and a 0 to the $\overline{\text{INT}}$ _Clear Bit (Bit 3) of the Configuration Register. $\overline{\text{INT}}$ _Enable (Bit 1) should be set to 1 to enable the $\overline{\text{INT}}$ output. The ADC measures each analog input in turn; as each measurement is completed, the result is automatically stored in the appropriate value register. This “round robin” monitoring cycle continues until it is disabled by writing a 0 to Bit 0 of the Configuration Register.

As the ADC will normally be left to free-run in this manner, the time taken to monitor all the analog inputs will normally not be of interest, as the most recently measured value of any input can be read out at any time.

For applications where the monitoring cycle time is important, it can be calculated as follows:

$$m \times t_1 + n \times t_2 \tag{eq. 6}$$

where:

m – the number of inputs configured as analog inputs, plus the internal V_{CC} measurement and internal temperature sensor.

t_1 – the time taken for an analog input conversion, nominally 6.044 ms.

n – the number of inputs configured as external temperature inputs.

t_2 – the time taken for a temperature conversion, nominally 33.24 ms.

This rapid sampling of the analog inputs ensures a quick response in the event of any input going out of limits, unlike other monitoring chips that employ slower ADCs.

Fan Monitoring Cycle Time

When a monitoring cycle is started, monitoring of the fan speed inputs begins at the same time as monitoring of the analog inputs. However, the two monitoring cycles are not synchronized in any way. The monitoring cycle time for the fan inputs is dependent on fan speed and is much slower than for the analog inputs. For more details, see the Fan Speed Measurement section.

Input Safety

Scaling of the analog inputs is performed on-chip, so external attenuators are normally not required. However, since the power supply voltages will appear directly at the pins, it is advisable to add small external resistors in series with the supply traces to the chip to prevent damaging the traces or power supplies should an accidental short such as a probe connect two power supplies together.

As the resistors will form part of the input attenuators, they will affect the accuracy of the analog measurement if their value is too high. The analog input channels are calibrated assuming an external series resistor of 500 Ω, and the accuracy will remain within specification for any value from 0 kΩ to 1 kΩ, so a standard 510 Ω resistor is suitable.

The worst such accident would be connecting –2.0 V to +12 V, a total of 24 V difference. With the series resistors, this would draw a maximum current of approximately 24 mA.

Analog Output

The ADM1024 has a single analog output from an unsigned 8-bit DAC that produces 0 V to 2.5 V. The analog output register defaults to FF during power-on reset, which produces maximum fan speed. The analog output may be amplified and buffered with external circuitry such as an op amp and transistor to provide fan speed control.

Suitable fan drive circuits are given in Figure 19 to Figure 24. When using any of these circuits, the following points should be noted:

1. All of these circuits will provide an output range from 0 V to almost 12 V, apart from Figure 25 which loses the base-emitter voltage drop of Q1 due to the emitter-follower configuration.
2. To amplify the 2.5 V range of the analog output up to 12 V, the gain of these circuits needs to be around 4.8.

3. Care must be taken when choosing the op amp to ensure that its input common-mode range and output voltage swing are suitable.
4. The op amp may be powered from the 12 V rail alone or from 12 V. If it is powered from 12 V, then the input common-mode range should include ground to accommodate the minimum output voltage of the DAC, and the output voltage should swing below 0.6 V to ensure that the transistor can be turned fully off.
5. If the op amp is powered from –12 V, precautions such as a clamp diode to ground may be needed to prevent the base-emitter junction of the output transistor being reverse-biased in the unlikely event that the output of the op amp should swing negative for any reason.

Figure 19. Fan Drive Circuit with Op Amp and Emitter-Follower

Figure 20. Fan Drive Circuit with Op Amp and PNP Transistor

Figure 21. Fan Driver Circuit with Op Amp and P-Channel MOSFET

Figure 22. Discrete Fan Drive Circuit with P-Channel MOSFET, Single Supply

Figure 23. Discrete Fan Drive Circuit with P-Channel MOSFET, Dual Supply

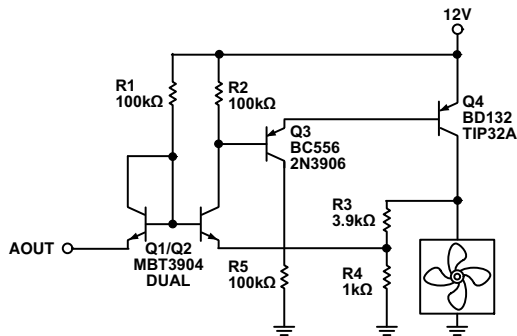

Figure 24. Discrete Fan Drive Circuit with Bipolar Output, Dual Supply

- In all these circuits, the output transistor must have an $I_{C_{MAX}}$ greater than the maximum fan current, and be capable of dissipating power due to the voltage dropped across it when the fan is not operating at full speed.
- If the fan motor produces a large back EMF when switched off, it may be necessary to add clamp diodes to protect the output transistors in the event that the output goes very quickly from full scale to zero.

Fault-Tolerant Fan Control

The ADM1024 incorporates a fault-tolerant fan control capability that can override the setting of the analog output and force it to maximum to give full fan speed in the event of a critical overtemperature problem even if, for some reason, this has not been handled by the system software.

There are four temperature set points that will force the analog output to FFh if any one of them is exceeded for three or more consecutive measurements. Two of these limits are programmable by the user and two are hardware limits intended as must not exceed limits that cannot be changed. The analog output will be forced to FFh if:

The temperature measured by the on-chip sensor exceeds the limit programmed into register address 13h;

or:

The temperature measured by either of the remote sensors exceeds the limit programmed into address 14h;

or:

The temperature measured by the on-chip sensor exceeds 70°C, which is hardware programmed into a read-only register at address 17h;

or:

The temperature measured by either of the remote sensors exceeds 85°C, which is hardware programmed into a read-only register at address 18h.

Once the hardware override of the analog output is triggered, it will return to normal operation only after three consecutive measurements that are 5 degrees lower than each of the above limits.

The analog output can also be forced to FFh by pulling the THERM pin (Pin 2) low.

The limits in Registers 13h and 14h can be programmed by the user. Obviously, these limits should not exceed the hardware values in Registers 17h and 18h, as they would have no effect. The power-on default values of these registers are the same as the two hardware registers, 70°C and 85°C, respectively, so there is no need to program them if these limits are acceptable.

Once these registers have been programmed, or if the defaults are acceptable, the values in these registers can be locked by writing a 1 to Bits 1 and 2 of Configuration Register 2 (address 4Ah). This prevents any unauthorized tampering with the limits. These lock bits can only be written to 1 and can only be cleared by power-on reset or by taking the RESET pin low, so registers 13h and 14h cannot be written to again unless the device is powered off, then on.

Layout and Grounding

Analog inputs will provide best accuracy when referred to a clean ground. A separate, low impedance ground plane for analog ground, which provides a ground point for the

voltage dividers and analog components, will provide best performance but is not mandatory.

The power supply bypass, the parallel combination of 10 μ F (electrolytic or tantalum) and 0.1 μ F (ceramic) bypass capacitors connected between Pin 9 and ground, should also be located as close as possible to the ADM1024.

Fan Inputs

Pins 5 and 6 may be configured as analog inputs or fan speed inputs by programming Bits 0 and 1 of the Channel Mode Register. The power-on default for these bits is all zeros, which makes Pins 5 and 6 fan inputs.

Signal conditioning in the ADM1024 accommodates the slow rise and fall times typical of fan tachometer outputs. The maximum input signal range is 0 to V_{CC} . In the event that these inputs are supplied from fan outputs that exceed 0 V to 6.5 V, either resistive attenuation of the fan signal or diode clamping must be included to keep inputs within an acceptable range.

Figure 25 to Figure 28 show circuits for most common fan tachometer outputs.

If the fan tachometer output has a resistive pullup to V_{CC} , it can be directly connected to the fan input, as shown in Figure 25.

Figure 25. Fan with Tach Pullup to $+V_{CC}$

If the fan output has a resistive pullup to 12 V (or other voltage greater than 6.5 V), the fan output can be clamped with a Zener diode, as shown in Figure 26. The Zener voltage should be chosen so it is greater than V_{IH} but less than 6.5 V, allowing for the voltage tolerance of the Zener. A value of between 3.0 V and 5.0 V is suitable.

*CHOOSE ZD1 VOLTAGE APPROXIMATELY $0.8 \times V_{CC}$.

Figure 26. Fan with Tach. Pullup to Voltage >6.5 V (e.g., 12 V) Clamped with Zener Diode

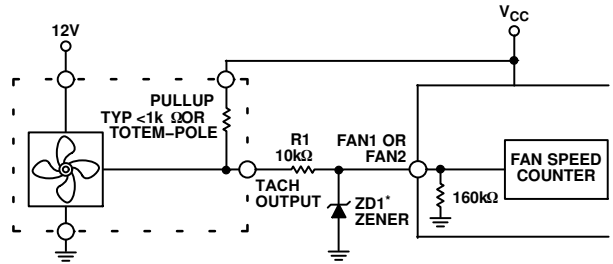

If the fan has a strong pullup (less than 1 k Ω) to 12 V, or a totem-pole output, then a series resistor can be added to limit the Zener current, as shown in Figure 27. Alternatively, a resistive attenuator may be used, as shown in Figure 28.

R1 and R2 should be chosen such that:

$$2.0 \text{ V} < V_{\text{PULLUP}} \times \frac{R2}{(R_{\text{PULLUP}} + R1 + R2)} < 5.0 \text{ V} \quad (\text{eq. 7})$$

The fan inputs have an input resistance of nominally 160 k Ω to ground, so this should be taken into account when calculating resistor values.

With a pullup voltage of 12 V and pullup resistor less than 1 k Ω , suitable values for R1 and R2 would be 100 k Ω and 47 k Ω . This will give a high input voltage of 3.83 V.

*CHOOSE ZD1 VOLTAGE APPROXIMATELY $0.8 \times V_{CC}$

Figure 27. Fan with Strong Tach Pullup to $>V_{CC}$ or Totem Pole Output, Clamped with Zener and Resistor

*SEE TEXT.

Figure 28. Fan with Strong Tach Pullup to $>V_{CC}$ or Totem Pole Output, Attenuated with R1/R2

Fan Speed Measurement

The fan counter does not count the fan tachometer output pulses directly because the fan speed may be less than 1000 rpm and it would take several seconds to accumulate a reasonably large and accurate count. Instead, the period of the fan revolution is measured by gating an on-chip 22.5 kHz oscillator into the input of an 8-bit counter for two periods of the fan tachometer output, as shown in Figure 29; the accumulated count is actually proportional to the fan tachometer period and inversely proportional to the fan speed.

Figure 29. Fan Speed Measurement

The monitoring cycle begins when a one is written to the Start Bit (Bit 0), and a zero to the INT_Clear Bit (Bit 3) of the Configuration Register. INT_Enable (Bit 1) should be set to one to enable the INT output. The measurement begins on the rising edge of a fan tachometer pulse, and ends on the next-but-one rising edge. The fans are monitored sequentially, so if only one fan is monitored, the monitoring time is the time taken after the Start Bit for it to produce two complete tachometer cycles or for the counter to reach full scale, whichever occurs sooner. If more than one fan is monitored, the monitoring time depends on the speed of the fans and the timing relationship of their tachometer pulses. This is illustrated in Figure 30. Once the fan speeds have been measured, they will be stored in the Fan Speed Value

Registers and the most recent value can be read at any time. The measurements will be updated as long as the monitoring cycle continues.

To accommodate fans of different speed and/or different numbers of output pulses per revolution, a prescaler (divisor) of 1, 2, 4, or 8 may be added before the counter. The default value is 2, which gives a count of 153 for a fan running at 4400 rpm, producing two output pulses per revolution.

The count is calculated by the equation:

$$\text{Count} = \frac{22.5 \times 10^3 \times 60}{\text{RPM} \times \text{Divisor}} \quad (\text{eq. 8})$$

For constant speed fans, fan failure is normally considered to have occurred when the speed drops below 70% of nominal, which would correspond to a count of 219. Full scale (255) would be reached if the fan speed fell to 60% of its nominal value. For temperature-controlled variable speed fans, the situation will be different.

Table 9 shows the relationship between fan speed and time per revolution at 60%, 70%, and 100% of nominal rpm for fan speeds of 1100, 2200, 4400, and 8800 rpm, and the divisor that would be used for each of these fans, based on two tachometer pulses per revolution.

FAN1 and FAN2 Divisors are programmed into Bits 4 to 7 of the VID0-3/Fan Divisor Register.

Table 9. FAN SPEEDS AND DIVISORS

Divisor	RPM	Nominal RPM	Time Per				
			Rev (ms)	70% RPM	Rev 70% (ms)	60% RPM	Rev 60% (ms)
÷ 1		8800	6.82	6160	9.74	5280	11.36
÷ 2		4400	13.64	3080	19.48	2640	22.73
÷ 4		2200	27.27	1540	38.96	1320	45.44
÷ 8		1100	54.54	770	77.92	660	90.90

Limit Values

Fans in general will not over-speed if run from the correct voltage, so the failure condition of interest is under-speed due to electrical or mechanical failure. For this reason only, low speed limits are programmed into the limit registers for the fans. It should be noted that, since fan period rather than speed is being measured, a fan failure interrupt will occur when the measurement exceeds the limit value.

Monitoring Cycle Time

The monitoring cycle time depends on the fan speed and number of tachometer output pulses per revolution. Two complete periods of the fan tachometer output (three rising edges) are required for each fan measurement. Therefore, if the start of a fan measurement just misses a rising edge, the measurement can take almost three tachometer periods. In order to read a valid result from the fan value registers, the total monitoring time allowed after starting the monitoring cycle should, therefore, be three tachometer periods of

FAN1 plus three tachometer periods of FAN2 at the lowest normal fan speed.

Although the fan monitoring cycle and the analog input monitoring cycle are started together, they are not synchronized in any other way.

Fan Manufacturers

Manufacturers of cooling fans with tachometer outputs are listed below:

NMB Tech

Chassis Intrusion Input

The chassis intrusion input is an active high input/open-drain output intended for detection and signalling of unauthorized tampering with the system. An external circuit powered from the system’s CMOS backup battery is used to detect and latch a chassis intrusion event, whether or not the system is powered up. Once a chassis intrusion has been detected and latched, the CI input will generate an interrupt when the system is powered up.

The actual detection of chassis intrusion is performed by an external circuit that will, for example, detect when the cover has been removed. A wide variety of techniques may be used for the detection, for example:

- Microswitch that Opens or Closes when the Cover is Removed
- Reed Switch Operated by Magnet Fixed to the Cover
- Hall-effect Switch Operated by Magnet Fixed to the Cover
- Phototransistor that Detects Light when the Cover is Removed

The chassis intrusion interrupt will remain asserted until the external detection circuit is reset. This can be achieved by setting Bit 7 of the Chassis Intrusion Clear Register to one, which will cause the CI pin to be pulled low for at least 20 ms. This register bit is self-clearing.

Figure 30. Chassis Intrusion Detector and Latch

The chassis intrusion circuit should be designed so that it can be reset by pulling its output low. A suitable chassis intrusion circuit using a photo-transistor is shown in Figure 30. Light falling on the photo-transistor when the PC cover is removed will cause it to turn on and pull up the input

of 1, thus setting the latch N3/N4. After the cover is replaced, a low reset on the CI output will pull down the input of N4, resetting the latch.

The chassis intrusion input can also be used for other types of alarm input. Figure 31 shows a temperature alarm circuit using an AD22105 temperature switch sensor. This produces a low going output when the preset temperature is exceeded, so the output is inverted by Q1 to make it compatible with the CI input. Q1 can be almost any small-signal NPN transistor, or a TTL or CMOS inverter gate may be used if one is available. See the AD22105 data sheet for information on selecting R_{SET}.

Figure 31. Using the CI Input with a Temperature Sensor

Note: The chassis intrusion input does not have a protective clamp diode to V_{CC}, as this could pull down the chassis intrusion latch and reset it when the ADM1024 is powered down.

The ADM1024 Interrupt Structure

The Interrupt Structure of the ADM1024 is shown in Figure 32. As each measurement value is obtained and stored in the appropriate value register, the value and the limits from the corresponding limit registers are fed to the high and low limit comparators. The result of each comparison (1 = out of limit, 0 = in limit) is routed to the corresponding bit input of the Interrupt Status Registers via a data demultiplexer and used to set that bit high or low as appropriate.

The Interrupt Mask Registers have bits corresponding to each of the Interrupt Status Register Bits. Setting an Interrupt Mask Bit high forces the corresponding Status Bit output low, while setting an Interrupt Mask Bit low allows the corresponding Status Bit to be asserted. After masking, the status bits are all OR'd together to produce the \overline{INT} output, which will pull low if any unmasked status bit goes high, i.e., when any measured value goes out of limit. The ADM1024 also has a dedicated output for temperature interrupts only, the \overline{THERM} input/output Pin 2. The function of this is described later.

The \overline{INT} output is enabled when Bit 1 of Configuration Register 1 ($\overline{INT_Enable}$) is high, and Bit 3 ($\overline{INT_Clear}$) is low. The \overline{INT} pin has an internal, 100 kΩ pullup resistor.

VID/IRQ Inputs

The processor voltage ID inputs VID0 to VID4 can be reconfigured as interrupt inputs by setting Bit 7 of the Channel Mode Register (address 16h). In this mode they

operate as level-triggered interrupt inputs, with VID0/IRQ0 to VID2/IRQ2 being active low and VID3/IRQ3 and VID4/IRQ4 being active high. The individual interrupt inputs can be enabled or masked by setting or clearing Bits 4 to 6 of the Channel Mode Register and Bits 6 and 7 of Configuration Register 2 (address 4Ah). These interrupt inputs are not latched in the ADM1024, so they do not require clearing as do bits in the Status Registers. However, the external interrupt source should be cleared once the interrupt has been serviced, or the interrupt request will be reasserted.

Interrupt Clearing

Reading an Interrupt Status Register will output the contents of the Register, then clear it. It will remain cleared until the monitoring cycle updates it, so the next read

operation should not be performed on the register until this has happened, or the result will be invalid. The time taken for a complete monitoring cycle is mainly dependent on the time taken to measure the fan speeds, as described earlier.

The $\overline{\text{INT}}$ output is cleared with the $\overline{\text{INT_Clear}}$ bit, which is Bit 3 of the Configuration Register, without affecting the contents of the Interrupt (INT) Status Registers.

Interrupt Status Mirror Registers

Whenever a bit in one of the Interrupt Status Registers is updated, the same bit is written to duplicate registers at addresses 4Ch and 42h. These registers allow a second management system to access the status data without worrying about clearing the data. The data in these registers is for reading only and has no effect on the interrupt output.

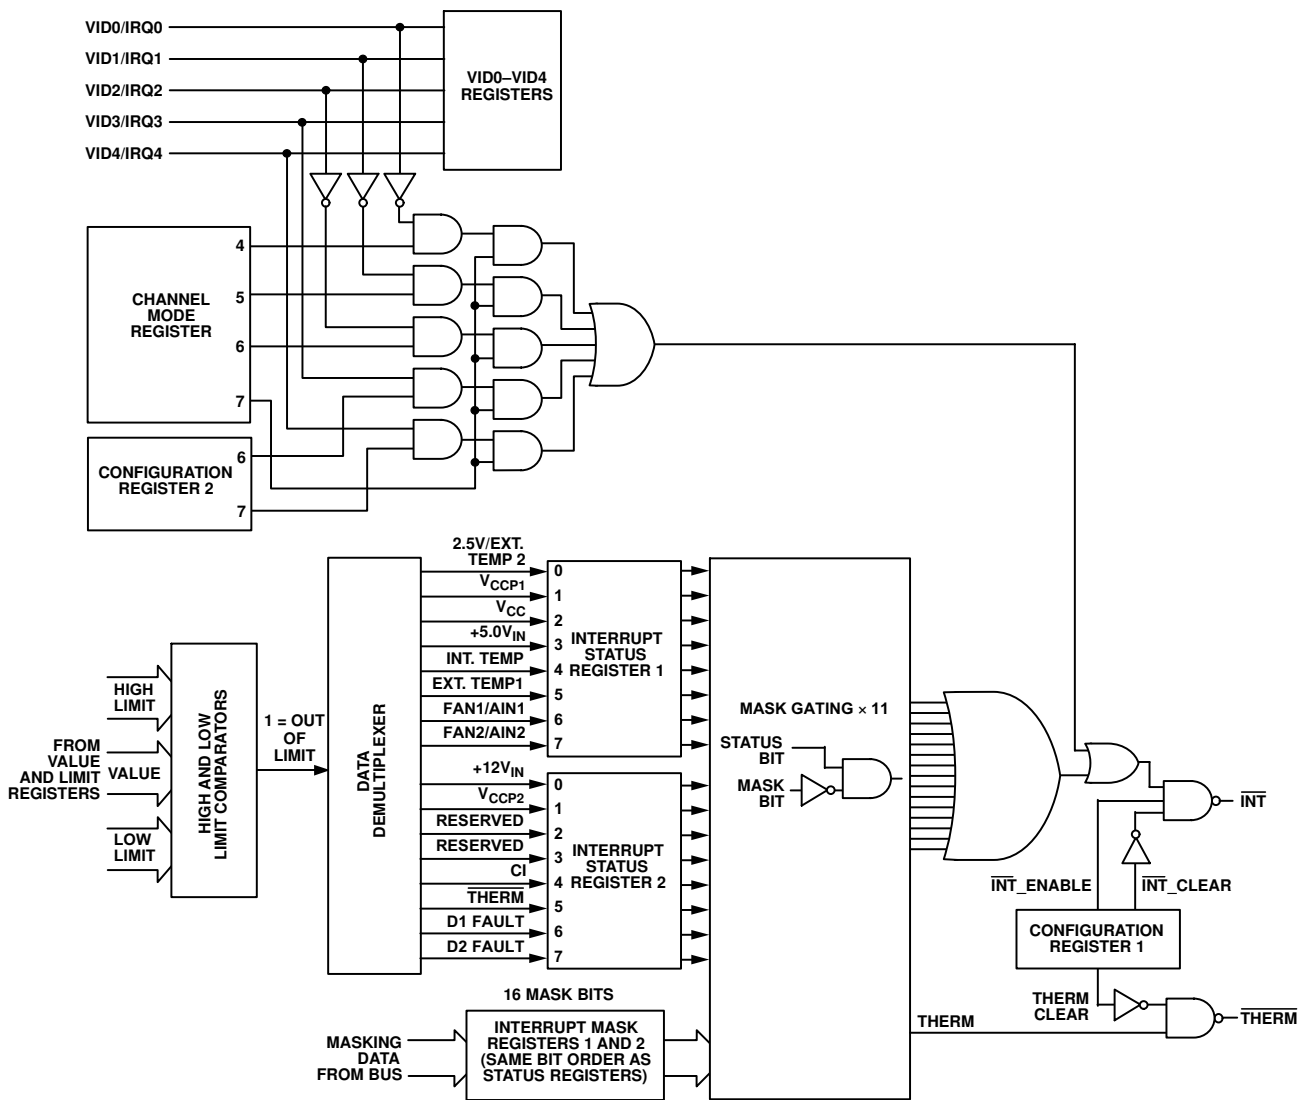

Figure 32. Interrupt Register Structure

Temperature Interrupt Modes

The ADM1024 has two distinct methods of producing interrupts for out-of-limit temperature measurements from the internal or external sensors. Temperature errors can generate an interrupt on the $\overline{\text{INT}}$ pin along with other interrupts, but there is also a separate $\overline{\text{THERM}}$ pin that generates an interrupt only for temperature errors.

Operation of the $\overline{\text{INT}}$ output for temperature interrupts is illustrated in Figure 33. Assuming that the temperature starts off within the programmed limits and that temperature interrupt sources are not masked, $\overline{\text{INT}}$ will go low if the temperature measured by any of the internal or external sensors exceeds the programmed high temperature limit for that sensor, or the hardware limits in register 13h, 14h, 17h, or 18h.

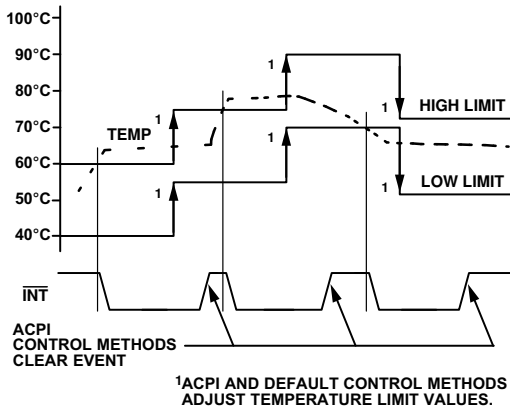

Figure 33. Operation of $\overline{\text{INT}}$ for Temperature Interrupts

Once the interrupt has been cleared, it will not be reasserted even if the temperature remains above the high limit(s). However, $\overline{\text{INT}}$ will be reasserted if:

The temperature falls below the low limit for the sensor;

or:

The high limit(s) is/are reprogrammed to a new value, and the temperature then rises above the new high limit on the next monitoring cycle;

or:

The $\overline{\text{THERM}}$ pin is pulled low externally, which sets Bit 5 of Interrupt Status Register 2;

or:

An interrupt is generated by another source.

Similarly, should the temperature measured by a sensor start off within limits then fall below the low limit, $\overline{\text{INT}}$ will be asserted. Once cleared, it will not be reasserted unless: The temperature rises above the high limit;

or:

The low limit(s) is/are reprogrammed, and the temperature then falls below the new low limit;

or:

The $\overline{\text{THERM}}$ pin is pulled low externally, which sets Bit 5 of Interrupt Status Register 2;

or:

An interrupt is generated by another source.

$\overline{\text{THERM}}$ Input/Output

The Thermal Management Input/Output ($\overline{\text{THERM}}$) is a logic input/output with an internal, 100 k Ω pullup resistor, that provides a separate output for temperature interrupts only. It is enabled by setting Bit 2 of Configuration Register 1. The $\overline{\text{THERM}}$ output has two operating modes that can be programmed by Bit 3 of Configuration Register 2 (address 4Ah). With this bit set to the default value of 0, the $\overline{\text{THERM}}$ output operates in “Default” interrupt mode. With this bit set to 1, the $\overline{\text{THERM}}$ output operates in “ACPI” mode.

Thermal interrupts can still be generated at the $\overline{\text{INT}}$ output while $\overline{\text{THERM}}$ is enabled, but if these are not required they can be masked by writing a 1 to Bit 0 of Configuration Register 2 (address 4Ah). The $\overline{\text{THERM}}$ pin can also function as a logic input for an external sensor, for example, a temperature sensor such as the ADM22105 used in Figure 35. If $\overline{\text{THERM}}$ is taken low by an external source, the analog output will be forced to FFh to switch a controlled fan to maximum speed. This also generates an $\overline{\text{INT}}$ output as previously described.

Default Mode

In Default mode, the $\overline{\text{THERM}}$ output operates like a thermostat with hysteresis. $\overline{\text{THERM}}$ will go low and Bit 5 of Interrupt Status Register 2 will be set, if the temperature measured by any of the sensors exceeds the high limit programmed for that sensor. It will remain asserted until reset by reading Interrupt Status Register 2, by setting Bit 6 of Configuration Register 1, or when the temperature falls below the low limit programmed for that sensor.

Figure 34. $\overline{\text{INT}}$ or $\overline{\text{THERM}}$ Output in Default Mode

If $\overline{\text{THERM}}$ is cleared by reading the status register, it will be reasserted after the next temperature reading and comparison if it remains above the high limit.

If $\overline{\text{THERM}}$ is cleared by setting Bit 6 of Configuration Register 1, it cannot be reasserted until this bit is cleared.

$\overline{\text{THERM}}$ will also be asserted if one of the hardware temperature limits at addresses 13h, 14h, 17h, or 18h is exceeded for three consecutive measurements. When this happens, the analog output will be forced to FFh to boost a controlled cooling fan to full speed.

Reading Status Register 1 will not clear $\overline{\text{THERM}}$ in this case, because errors caused by exceeding the hardware

temperature limits are stored in a separate register that is not cleared by reading the status register. In this case, $\overline{\text{THERM}}$ can only be cleared by setting Bit 0 of Configuration Register 2.

$\overline{\text{THERM}}$ will be cleared automatically if the temperature falls at least 5 degrees below the limit for three consecutive measurements.

ACPI Mode

In ACPI mode, $\overline{\text{THERM}}$ responds only to the hardware temperature limits at addresses 13h, 14h, 17h, and 18h, not to the software-programmed limits.

Figure 35. $\overline{\text{THERM}}$ Output in ACPI Mode

$\overline{\text{THERM}}$ will go low if either the internal or external hardware temperature limit is exceeded for three consecutive measurements. It will remain low until the temperature falls at least 5 degrees below the limit for three consecutive measurements. While $\overline{\text{THERM}}$ is low, the analog output will go to FFh to boost a controlled fan to full speed.

RESET Input/Output

$\overline{\text{RESET}}$ (Pin 12) is an I/O pin that can function as an open-drain output, providing a low going 20 ms output pulse when Bit 4 of the Configuration Register is set to 1, provided the reset function has first been enabled by setting Bit 7 of Interrupt Mask Registers 2 to 1. The bit is automatically cleared when the reset pulse is output. Pin 11 can also function as a $\overline{\text{RESET}}$ input by pulling this pin low to reset the internal registers of the ADM1024 to default values. Only those registers that have power-on default values as listed in Table 10 are affected by this function. The DAC, Value, and Limit Registers are not affected.

NAND Tree Tests

A NAND gate is provided in the ADM1024 for Automated Test Equipment (ATE) board level connectivity testing. The device is placed into NAND Test Mode by powering up with Pin 11 held high. This pin is automatically sampled after powerup; if it is connected high, then the NAND test mode is invoked.

In NAND test mode, all digital inputs may be tested as illustrated below. $\overline{\text{NTEST_OUT/ADD}}$ will become the NAND test output pin. To perform a NAND tree test, all pins included in the NAND tree should first be driven high. Each

pin can then be toggled and a resulting toggle can be observed on $\overline{\text{NTEST_OUT/ADD}}$.

Allow for a typical propagation delay of 500 ns. The structure of the NAND tree is shown in Figure 36.

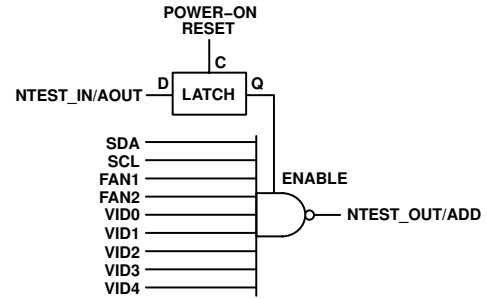

Figure 36. NAND Tree

Note that $\overline{\text{NTEST_OUT/ADD}}$ is a dual function line and if both functions are required, then this line should not be hardwired directly to VCC/GND. Instead it should be connected via a 5 kΩ resistor.

Note: If any of the inputs shown in Figure 36 are unused, they should not be connected directly to ground, but via a resistor such as 10 kΩ. This will allow the Automatic Test Equipment (ATE) to drive every input high so that the NAND tree test can be carried out properly.

Using the ADM1024

Power-on Reset

When power is first applied, the ADM1024 performs a power-on reset on several of its registers. Registers whose power-on values are not shown have power-on conditions that are indeterminate (this includes the Value and Limit Registers). The ADC is inactive. In most applications, usually the first action after power-on would be to write limits into the Limit Registers. Power-on reset clears or initializes the following registers (the initialized values are shown in Table 12):

- Configuration Registers 1 and 2
- Channel Mode Register
- Interrupt ($\overline{\text{INT}}$) Status Registers 1 and 2
- Interrupt ($\overline{\text{INT}}$) Status Mirror Registers 1 and 2
- Interrupt ($\overline{\text{INT}}$) Mask Registers 1 and 2
- VID/Fan Divisor Register
- VID4 Register
- Chassis Intrusion Clear Register
- Test Register
- Analog Output Register
- Hardware Trip Registers

Initialization

Configuration Register initialization performs a similar, but not identical, function to power-on reset. The Test Register and Analog Output Register are not initialized.

Configuration Register initialization is accomplished by setting Bit 7 of the Configuration Register high. This bit automatically clears after being set.

Using the Configuration Registers

Control of the ADM1024 is provided through two configuration registers. The ADC is stopped upon powerup, and the $\overline{\text{INT}}$ _Clear signal is asserted, clearing the $\overline{\text{INT}}$ output. The Configuration Registers are used to start and stop the ADM1024; enable or disable interrupt outputs and modes, and provide the initialization function described above.

Bit 0 of Configuration Register 1 controls the monitoring loop of the ADM1024. Setting Bit 0 low stops the monitoring loop and puts the ADM1024 into a low power mode thereby reducing power consumption. Serial bus communication is still possible with any register in the ADM1024 while in low power mode. Setting Bit 0 high starts the monitoring loop.

Bit 1 of Configuration Register 1 enables or disables the $\overline{\text{INT}}$ Interrupt output. Setting Bit 1 high enables the $\overline{\text{INT}}$ output; setting Bit 1 low disables the output.

Bit 2 of Configuration Register 1 enables or disables the $\overline{\text{THERM}}$ output. Setting Bit 1 high enables the $\overline{\text{INT}}$ output; setting Bit 1 low disables the output.

Bit 3 of Configuration Register 1 is used to clear the $\overline{\text{INT}}$ interrupt output when set high. The ADM1024 monitoring function will stop until Bit 3 is set low. Interrupt Status register contents will not be affected.

Bit 4 of Configuration Register 1 causes a low going 45 ms (typ) pulse at the $\overline{\text{RESET}}$ pin (Pin 12).

Bit 6 of Configuration Register 1 is used to clear an interrupt at the $\overline{\text{THERM}}$ output when it is set to 1.

Bit 7 of Configuration Register 1 is used to start a Configuration Register Initialization when it is set to 1.

Bit 0 of Configuration Register 2 is used to mask temperature interrupts at the $\overline{\text{INT}}$ output when it is set to 1. The $\overline{\text{THERM}}$ output is unaffected by this bit.

Bits 1 and 2 of Configuration Register 2 lock the values stored in the Local and Remote Fan Control Registers at addresses 13h and 14h. The values in these registers cannot be changed until a power-on reset is performed.

Bit 3 of Configuration Register 2 selects the $\overline{\text{THERM}}$ interrupt mode. The default value of 0 selects one-time mode. Setting this bit to 1 selects ACPI mode.

Starting Conversion

The monitoring function (analog inputs, temperature, and fan speeds) in the ADM1024 is started by writing to Configuration Register 1 and setting Start (Bit 0) high. The $\overline{\text{INT}}$ _Enable (Bit 1) should be set to 1, and INT Clear (Bit 3) set to 0 to enable interrupts. The $\overline{\text{THERM}}$ Enable bit (Bit 2) should be set to 1 and the $\overline{\text{THERM}}$ Clear bit (Bit 6) should be set to 0 to enable temperature interrupts at the $\overline{\text{THERM}}$ pin. Apart from initially starting together, the analog measurements and fan speed measurements proceed independently, and are not synchronized in any way.

The time taken to complete the analog measurements depends on how they are configured, as described elsewhere. The time taken to complete the fan speed measurements depends on the fan speed and the number of tachometer output pulses per revolution.

Once the measurements have been completed, the results can be read from the Value Registers at any time.

Reduced Power and Shutdown Mode

The ADM1024 can be placed in a low power mode by setting Bit 0 of the Configuration Register to 0. This disables the internal ADC. Full shutdown mode may then be achieved by setting Bit 0 of the Test Register to 1. This turns off the analog output and stops the monitoring cycle, if running, but does not affect the condition of any of the registers. The device will return to its previous state when this bit is reset to 0.

Application Circuit

Figure 37 shows a generic application circuit using the ADM1024. The analog monitoring inputs are connected to the power supplies including two processor core voltage inputs. The VID inputs are connected to the processor voltage ID pins. There are two tachometer inputs from fans, and the analog output is used to control the speed of a third fan. An opto-sensor for chassis intrusion detection is connected to the CI input. Of course, in an actual application, every input and output may not be used, in which case unused analog and digital inputs should be tied to analog or digital ground as appropriate.

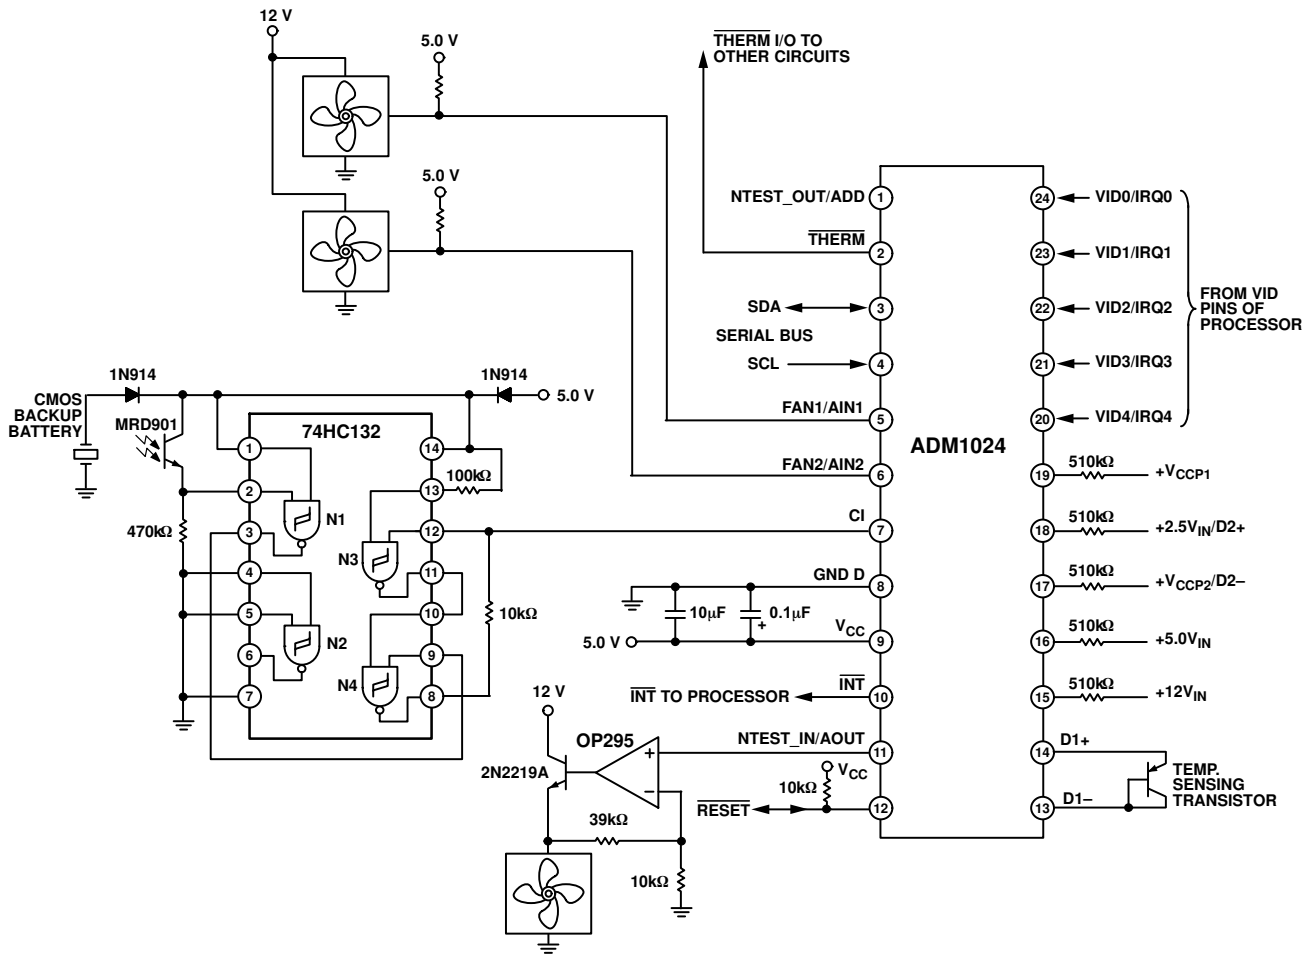

Figure 37. Application Circuit

ADM1024

ADM REGISTERS

Table 10. ADDRESS POINTER REGISTER

Bit	Name	R/W	Description
7–0	Address Pointer	W	Address of ADM1024 registers. See the following tables for details.

Table 11. LIST OF REGISTERS

Hex Addr	Description	Power-on Value (Binary Bit 7–0)	Notes
13h	Internal Temperature Hardware Trip Point	= 70°C	Can be written only if the write once bit in Configuration Register 2 has not been set. Values higher than 70°C will have no affect as the fixed trip point in register 16h will be reached first.
14h	External Temperature Hardware Trip Point	= 85°C	Can be written only if the write once bit in Configuration Register 2 has not been set. Values higher than 85°C will have no affect as the fixed trip point in register 17h will be reached first.
15h	Test Register	0000 00X0	Setting Bit 0 of this register to 1 selects shutdown mode. Caution: Do not write to any other bits in this register.
16h	Channel Mode Register	0000 0000	This register configures the input channels and configures VID0 to VID4 as processor voltage ID or interrupt inputs.
17h	Internal Temperature Fixed Hardware Trip Point	= 70°C	Read Only. Cannot be changed.
18h	External Temperature Fixed Hardware Trip Point	= 85°C	Read Only. Cannot be changed.
19h	Programmed Value of Analog Output	1111 1111	
1Ah	A _{IN1} Low Limit	Indeterminate	
1Bh	A _{IN2} Low Limit	Indeterminate	
20h	2.5 V Measured Value/Ext. Temp2	Indeterminate	Read Only
21h	V _{CCP1} Measured Value	Indeterminate	Read Only
22h	V _{CC} Measured Value	Indeterminate	Read Only
23h	5.0 V Value	Indeterminate	Read Only
24h	12 V Measured Value	Indeterminate	Read Only
25h	V _{CCP2} Measured Value	Indeterminate	Read Only
26h	Ext. Temp1 Value	Indeterminate	Read Only. Stores the measurement from a diode sensor connected to Pins 13 and 14.
27h	Internal Temperature Value	Indeterminate	Read Only. This register is used to store eight bits of the internal temperature reading.
28h	FAN1/A _{IN1} Value	Indeterminate	Read Only. Stores FAN1 or AIN1 reading, depending on the configuration of Pin 5.
29h	FAN2/A _{IN1} Value	Indeterminate	Read Only. Stores FAN2 or AIN2 reading, depending on the configuration of Pin 6.
2Ah	Reserved	Indeterminate	
2Bh	2.5 V/Ext. Temp2 High Limit	Indeterminate	Stores high limit for 2.5 V input or, in temperature mode, this register stores the high limit for a diode sensor connected to Pins 17 and 18.
2Ch	2.5 V/Ext. Temp2 Low Limit	Indeterminate	Stores low limit for 2.5 V input or, in temperature mode, this register stores the low limit for a diode sensor connected to Pins 17 and 18.
2Dh	V _{CCP1} High Limit	Indeterminate	
2Eh	V _{CCP1} Low Limit	Indeterminate	
2Fh	V _{CC} High Limit	Indeterminate	
30h	V _{CC} Low Limit	Indeterminate	
31h	5.0 V High Limit	Indeterminate	
32h	5.0 V Low Limit	Indeterminate	
33h	12 V High Limit	Indeterminate
