

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from, Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Continuous Rate 6.5 Mbps to 11.3 Gbps Clock and Data Recovery IC with Integrated Limiting Amp/EQ

Data Sheet ADN2915

FEATURES

Serial data input: 6.5 Mbps to 11.3 Gbps

No reference clock required

Exceeds SONET/SDH requirements for jitter

transfer/generation/tolerance

Quantizer sensitivity: 7.3 mV typical (limiting amplifier mode)

Optional limiting amplifier, equalizer, and bypass inputs

Programmable jitter transfer bandwidth to support G.8251 OTN

Programmable slice level

Sample phase adjust (5.65 Gbps or greater)

Output polarity invert

Programmable LOS threshold via I²C

I²C to access optional features

Loss of signal (LOS) alarm (limiting amplifier mode only)

Loss of lock (LOL) indicator

PRBS generator/detector

Application-aware power

430 mW at 11.3 Gbps, equalizer enabled, no clock output 380 mW at 6.144 Gbps, limiting amplifier mode, no clock output

340 mW at 622 Mbps, input bypass mode, no clock output

Power supply: 1.2 V, flexible 1.8 V to 3.3 V, and 3.3 V

4 mm × 4 mm 24-lead LFCSP

APPLICATIONS

SONET/SDH OC-1/OC-3/OC-12/OC-48/OC-192 and all associated FEC rates

1GFC, 2GFC, 4GFC, 8GFC, 10GFC, 1GE, and 10GE

WDM transponders

Any rate regenerators/repeaters

GENERAL DESCRIPTION

The ADN2915 provides the receiver functions of quantization, signal level detect, and clock and data recovery for continuous data rates from 6.5 Mbps to 11.3 Gbps. The ADN2915 automatically locks to all data rates without the need for an external reference clock or programming. ADN2915 jitter performance exceeds all jitter specifications required by SONET/SDH, including jitter transfer, jitter generation, and jitter tolerance.

The ADN2915 provides manual or automatic slice adjust and manual sample phase adjusts. Additionally, the user can select a limiting amplifier, equalizer, or bypass at the input. The equalizer is either adaptive or can be manually set.

The receiver front-end loss of signal (LOS) detector circuit indicates when the input signal level has fallen below a user-programmable threshold. The LOS detect circuit has hysteresis to prevent chatter at the LOS output. In addition, the input signal strength can be read through the I²C registers.

The ADN2915 also supports pseudorandom binary sequence (PRBS) generation, bit error detection, and input data rate readback features.

The ADN2915 is available in a compact 4 mm \times 4 mm, 24-lead chip scale package (LFCSP). All ADN2915 specifications are defined over the ambient temperature range of -40° C to $+85^{\circ}$ C, unless otherwise noted.

See Figure 40.
 Fibre Channel Physical Interface 4 standard, FC-P1-4, Rev 8.00, May 21, 2008.
 When ac-coupled, the LOS assert and deassert times are dominated by the RC time constant of the ac coupling capacitor and the 100 Ω differential input termination of the ADN2915 input stage.
 This typical acquisition specification applies to all selectable reference clock frequencies in the range of 11.05 MHz to 176.8 MHz.

¹ Fibre Channel Physical Interface 4 standard, FC-P1-4, Rev 8.00, May 21, 2008. ² C_b is the total capacitance of one bus line in picofarads (pF). If mixed with high speed (HS) mode devices, faster rise/fall times are allowed (refer to the Philips *I*²*C Bus Specification*, Version 2.1).

³ Required accuracy in dc-coupled mode is guaranteed by design as long as the clock common-mode voltage output matches the reference clock commonmode voltage range.

TIMING DIAGRAMS

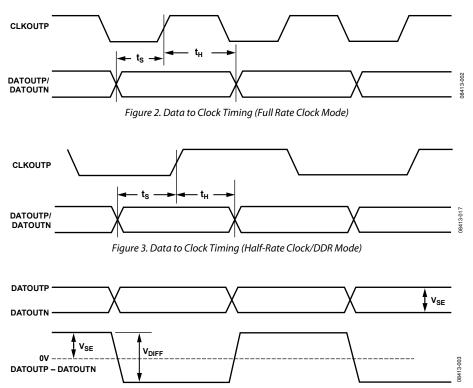

Figure 4. Single-Ended vs. Differential Output Amplitude Relationship

ABSOLUTE MAXIMUM RATINGS

Table 4.

1 0010 10	
Parameter	Rating
Supply Voltage (VCC = 1.2 V)	1.26 V
Supply Voltage (VDD and VCC1 = 3.3 V)	3.63 V
Maximum Input Voltage (REFCLKP/REFCLKN, NIN/PIN)	1.26 V
Minimum Input Voltage (REFCLKP/REFCLKN, NIN/PIN)	V _{EE} – 0.4 V
Maximum Input Voltage (SDA, SCK, I ² C_ADDR)	3.63 V
Minimum Input Voltage (SDA, SCK, I^2C_ADDR)	V _{EE} - 0.4 V
Maximum Junction Temperature	125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10 sec)	300°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL CHARACTERISTICS

Thermal Resistance

Thermal resistance is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages, for a 4-layer board with the exposed paddle soldered to VEE.

Table 5. Thermal Resistance

1 WO 10 CV 1 11 W1 11 W1 11 W1 11 W1 11 W1 11 W1 W						
Package Type	θ_{JA}^{1}	θ_{JB}^{2}	θ_{JC}^{3}	Unit		
24-Lead LFCSP	45	5	11	°C/W		

¹ Junction to ambient.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

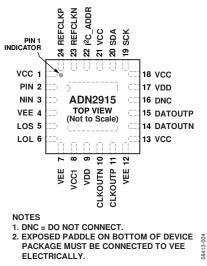

Figure 5. Pin Configuration

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Type ¹	Description			
1	VCC	Р	1.2 V Supply for Limiting Amplifier.			
2	PIN	Al	Positive Differential Data Input (CML).			
3	NIN	Al	egative Differential Data Input (CML).			
4	VEE	Р	Ground for Limiting Amplifier.			
5	LOS	DO	Loss of Signal Output (Active High).			
6	LOL	DO	Loss of Lock Output (Active High).			
7	VEE	Р	Digital Control Oscillator (DCO) Ground.			
8	VCC1	Р	1.8 V to 3.3 V DCO Supply.			
9	VDD	Р	3.3 V High Supply.			
10	CLKOUTN	DO	Negative Differential Recovered Clock Output (CML).			
11	CLKOUTP	DO	Positive Differential Recovered Clock Output (CML).			
12	VEE	Р	Ground for CML Output Drivers.			
13	VCC	Р	1.2 V Supply for CML Output Drivers.			
14	DATOUTN	DO	Negative Differential Retimed Data Output (CML).			
15	DATOUTP	DO	Positive Differential Retimed Data Output (CML).			
16	DNC	DI	Do Not Connect. Tie off to ground.			
17	VDD	Р	3.3 V High Supply.			
18	VCC	Р	1.2 V Core Digital Supply.			
19	SCK	DI	Clock for I ² C.			
20	SDA	DIO	Bidirectional Data for I ² C.			
21	VCC	Р	1.2 V Core Supply.			
22	I ² C_ADDR	DI	Sets the device I^2C address = 0x80 when $I^2C_ADDR = 0$, and the device I^2C address = 0x82 when $I^2C_ADDR = 1$.			
23	REFCLKN	DI	Negative Reference Clock Input (Optional).			
24	REFCLKP	DI	Positive Reference Clock Input (Optional).			
	EPAD	Р	Exposed Pad (VEE). The exposed pad on the bottom of the device package must be connected to VEE electrically. The exposed pad works as a heat sink.			

 $^{^{1}}$ P = power, AI = analog input, DI = digital input, DO = digital output, DIO = digital input/output.

TYPICAL PERFORMANCE CHARACTERISTICS

 $T_A = 25$ °C, VCC = 1.2 V, VCC1 = 1.8 V, VDD = 3.3 V, VEE = 0 V, input data pattern: PRBS $2^{15} - 1$, ac-coupled inputs and outputs, unless otherwise noted.

		0xC = 575 mV.
		0xD = 610 mV.
		0xE = 640 mV.
		0xF = 655 mV.

THEORY OF OPERATION

The ADN2915 implements a clock and data recovery for data rates between 6.5 Mbps and 11.3 Gbps. A front end is configurable to either amplify or equalize the nonreturn-to-zero (NRZ) input waveform to full-scale digital logic levels, or to bypass a full digital logic signal.

The user can choose among three input stages to process the data: a high gain limiting amplifier with better than 10~mV sensitivity, a high-pass passive equalizer with up to 10~dB of boost at 5~GHz, or a bypass buffer with 600~mV sensitivity.

An on-chip loss of signal (LOS) detector works with the high sensitivity limiting amplifier. The default threshold for the LOS is the sensitivity of the part, with a maximum threshold level of 128 mV p-p. The limiting amplifier slice threshold can use a factory trim setting, a user-defined threshold set by the $\rm I^2C$, or an adjusted level for the best eye opening at the phase detector.

When the input signal is corrupted due to FR-4 or other impairments in the PCB traces, a passive equalizer can be one of the signal integrity options. The equalizer high frequency boost is configurable through the I²C registers, in place of the factory default settings. A user-enabled adaptation is included that automatically adjusts the equalizer to achieve the widest eye opening. The equalizer can be manually set for any data rate, but adaptation is available only at data rates greater than 5.5 Gbps.

When a signal presents to the clock and data recovery (CDR), the ADN2915 is a delay-locked and phase-locked loop circuit for clock recovery and data retiming from an NRZ encoded data stream. Input data is sampled by a high speed clock. A digital downsampler accommodates data rates spanning three orders of magnitude. Downsampled data is applied to a binary phase detector.

The phase of the input data signal is tracked by two separate feedback loops. A high speed delay-locked loop path cascades a digital integrator with a digitally controlled phase shifter on the digital control oscillator (DCO) clock to track the high frequency components of jitter. A separate phase control loop composed of a digital integrator and DCO tracks the low

frequency components of jitter. The initial frequency of the DCO is set by a third loop that compares the DCO frequency with the input data frequency. This third loop also sets the decimation ratio of the digital downsampler.

The delay-locked and phase-locked loops together track the phase of the input data. For example, when the clock lags the input data, the phase detector drives the DCO to higher frequency and decreases the delay of the clock through the phase shifter; both of these actions serve to reduce the phase error between the clock and data. Because the loop filter is an integrator, the static phase error is driven to zero.

Another view of the circuit is that the phase shifter implements the zero required for frequency compensation of a second-order phase-locked loop, and this zero is placed in the feedback path and, thus, does not appear in the closed-loop transfer function. Because this circuit has no zero in the closed-loop transfer, jitter peaking is eliminated.

The delay-locked and phase-locked loops, together, simultaneously provide wideband jitter accommodation and narrow-band jitter filtering. The simplified block diagram in Figure 25 shows that Z(s)/X(s) is a second-order low-pass jitter transfer function that provides excellent filtering. The low frequency pole is formed by dividing the gain of the PLL by the gain of the DLL, where the upsampling and zero-order hold in the DLL has a gain approaching N at the transfer bandwidth of the loop. Note that the jitter transfer has no zero, unlike an ordinary second-order phase-locked loop. This means that the main PLL loop has no jitter peaking. This makes the circuit ideal for signal regenerator applications, where jitter peaking in a cascade of regenerators can contribute to hazardous jitter accumulation.

The error transfer, e(s)/X(s), has the same high-pass form as an ordinary phase-locked loop up to the slew rate limit of the DLL with a binary phase detector. This transfer function is free to be optimized to give excellent wideband jitter accommodation because the jitter transfer function, Z(s)/X(s), provides the narrow-band jitter filtering.

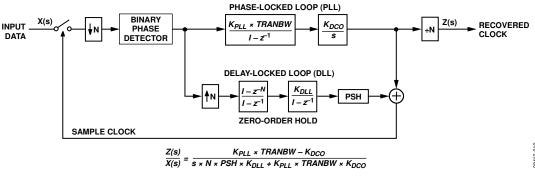

Figure 25. CDR Jitter Block Diagram

The delay-locked and phase-locked loops contribute to overall jitter accommodation. At low frequencies of input jitter on the data signal, the integrator in the loop filter provides high gain to track large jitter amplitudes with small phase error. In this case, the oscillator is frequency modulated and jitter is tracked as in an ordinary phase-locked loop. The amount of low frequency jitter that can be tracked is a function of the DCO tuning range. A wider tuning range gives larger accommodation of low frequency jitter. The internal loop control word remains small for small jitter frequency, so that the phase shifter remains close to the center of its range and, thus, contributes little to the low frequency jitter accommodation.

At medium jitter frequencies, the gain and tuning range of the DCO are not large enough to track input jitter. In this case, the DCO control word becomes large and saturates. As a result, the DCO frequency dwells at an extreme of its tuning range. The

size of the DCO tuning range, therefore, has only a small effect on the jitter accommodation. The delay-locked loop control range is now larger; therefore, the phase shifter takes on the burden of tracking the input jitter. An infinite range phase shifter is used on the clock. Consequently, the minimum range of timing mismatch between the clock at the data sampler and the retiming clock at the output is limited to 32 UI by the depth of the FIFO.

There are two ways to acquire the data rate. The default mode frequency locks to the input data, where a finite state machine extracts frequency measurements from the data to program the DCO and loop division ratio so that the sampling frequency matches the data rate to within 250 ppm. The PLL is enabled, driving this frequency difference to 0 ppm. The second mode is lock to reference, in which case the user provides a reference clock between 11.05 MHz and 176.8 MHz. Division ratios must be written to a serial port register.

FUNCTIONAL DESCRIPTION

FREQUENCY ACQUISITION

The ADN2915 acquires frequency from the data over a range of data frequencies from 6.5 Mbps to 11.3 Gbps. The lock detector circuit compares the frequency of the DCO and the frequency of the incoming data. When these frequencies differ by more than 1000 ppm, LOL is asserted and a new frequency acquisition cycle is initiated. The DCO frequency is reset to the bottom of its range, and the internal division rate is set to its lowest value of N = 1, which is the highest octave of data rates. The frequency detector then compares this sampling rate frequency to the data rate frequency and either increases N by a factor of 2 if the sampling rate frequency is found to be greater than the data rate frequency, or increases the DCO frequency if the data rate frequency is found to be greater than the data sampling rate. Initially, the DCO frequency is incremented in large steps to aid fast acquisition. As the DCO frequency approaches the data frequency, the step size is reduced until the DCO frequency is within 250 ppm of the data frequency, at which point LOL is deasserted.

When LOL is deasserted, the frequency-locked loop is turned off. The PLL or DLL pulls in the DCO frequency until the DCO frequency equals the data frequency.

LIMITING AMPLIFIER

The limiting amplifier has differential inputs (PIN and NIN) that are each internally terminated with 50 Ω to an on-chip voltage reference ($V_{\rm CM}$ = 0.95 V typically). The inputs must be ac-coupled. Input offset is factory trimmed to achieve better than 10 mV p-p typical sensitivity with minimal drift. The limiting amplifier can be driven differentially or single-ended. DC coupling of the limiting amplifier is not possible because the user needs to supply a common-mode voltage to exactly match the internal common-mode voltage; otherwise, the internal 50 Ω termination resistors absorb the difference in common-mode voltages.

Another reason the limiting amplifier cannot be dc-coupled is that the factory trimmed input offset becomes invalid. The offset is adjusted to zero by differential currents from the slice adjust DAC (see Figure 1). With ac coupling, all of the current goes to the 50 Ω termination resistors on the ADN2915. However, with dc coupling, this current is shared with the external drive circuit, and calibration of the offset is lost. In addition, the slice adjust must have all the current from the slice adjust DAC go to the resistors; otherwise, the calibration is lost (see the Slice Adjust section).

SLICE ADJUST

The quantizer slicing level can be offset by ± 100 mV in 1.6 mV steps or ± 15 mV in 0.24 mV steps to mitigate the effect of amplified spontaneous emission (ASE) noise or duty cycle distortion. Quantizer slice adjust level is set by the slice[6:0] bits in I²C Register 0x15.

Accurate control of the slice threshold requires the user to read back the factory trimmed offset, which is stored as a 7-bit number in the I^2C slice readback register (Register 0x73). Use Table 20 to decode the measured offset of the part, where an LSB corresponds to 0.24 mV.

Table 20. Program Slice Level, Normal Slice Mode (Extended Slice = 0)

Slice[6:0]	Decimal Value	Offset
0000000	0	Slice function disabled
0000001	1	−15 mV
•••		
1000000	64	0 mV
1111111	127	+14.75 mV

The amount of offset required for manual slice adjust is determined by subtracting the offset of the part from the desired slice adjust level. Use Table 20 or Table 21 to determine the code word to be written to the $\rm I^2C$ slice register.

An extended slice with coarser granularity for each LSB step is found in Table 21. Setting the extended slice bit (Bit 7) = 1 in Register 0x15 scales the full-scale range of the slice adjust by a factor of 6.

Table 21.Program Slice Level, Extended Slice Mode (Extended Slice = 1)

,				
Slice[6:0]	Decimal Value	Offset		
0000000	128	Slice function disabled		
0000001	129	−100 mV		
•••	•••			
1000000	192	0 mV		
1111111	255	+100 mV		

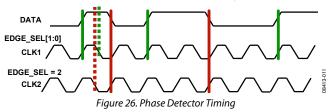

When manual slice is desired, disable the dc offset loop, which drives duty cycle distortion on the data to 0. Adaptive slice is disabled by setting ADAPTIVE_SLICE_EN = 0 in the DPLLD register (0x13).

EDGE SELECT

A binary or Alexander phase detector drives both the DLL and PLL loops at all division rates. Duty cycle distortion on the received data leads to a dead band in the phase detector transfer function if phase errors are measured on both rising and falling data transitions. This dead band leads to jitter generation of unknown spectral composition whose peak-to-peak amplitude is potentially large.

The recommended usage of the part when the dc offset loop is disabled computes phase errors exclusively on either the rising data edges with EDGE_SEL[1:0] (DPLLA[4:3]) = 1 (decimal) or falling data edges with EDGE_SEL[1:0] = 2 in Register 0x10. The alignment of the clock to the rising data edges with EDGE_SEL[1:0] = 1 is represented by the top two curves in

Figure 26. Duty cycle distortion with Narrow 1s moves the significant sampling instance where data is sampled to the right of center. The alignment of the clock to the falling data edges with EDGE_SEL[1:0] = 2 is represented by the first and third curves in Figure 26. The significant sampling instance moves to the left of center. Sample phase adjust for rates above 5.65 Gbps can be used to move the significant sampling instance to the center of the Narrow 1 (or Narrow 0) for best jitter tolerance.

DLL Slew

Jitter tolerance beyond the transfer bandwidth of the CDR is determined by the slew rate of the delay-locked loop implementing a delta modulator on phase. Setting DLL_SLEW[1:0] = 2, the default value, in the DPLLD register (Register 0x13) configures the DLL to track 0.75 UI p-p jitter at the highest frequency breakpoint in the SONET/SDH jitter tolerance mask. This frequency scales with the rate as f_{p4} = Rate (Hz)/2500 (for example, 4 MHz for OC-192). Peak-to-peak tracking in UI at f_{p4} obeys the expression (1 + DLL_SLEW)/4 UI p-p.

In some applications, full SONET/SDH jitter tolerance is not needed. In this case, DPLLD[1:0] can be set to 0, giving lower jitter generation on the recovered clock and better high frequency jitter tolerance.

Sample Phase Adjust

The phase of the sampling instant can be adjusted over the I²C when operating at data rates 5.65 Gbps or higher by writing to the SAMPLE_PHASE[3:0] bits (Phase[3:0]) in Register 0x14. This feature allows the user to adjust the sampling instant with the intent of improving the BER and jitter tolerance. Although the default sampling instant chosen by the CDR is sufficient in most applications, when dealing with some degraded input signals, the BER and jitter tolerance performance can be improved by manually adjusting the phase.

There is a total adjustment range of 0.5 UI, with 0.25 UI in each direction, in increments of 1/32 UI. SAMPLE_PHASE[3:0] is a twos complement number, and the relationship between data and the sampling clock is shown in Figure 28.

Transfer Bandwidth

The transfer bandwidth can be adjusted over the I²C by writing to TRANBW[2:0] in the DPLLA register (Register 0x10). The default value is 4. When set to values below 4, the transfer bandwidth is reduced, and when set to values above 4, the transfer bandwidth is increased. The resulting transfer bandwidth is based on the following formula:

$$Transfer\ BW = (Default\ Transfer\ BW) \times \left(\frac{TRANBW[2:0]}{4}\right)$$

For example, at OC-192, the default transfer bandwidth is 2 MHz. The resulting transfer bandwidth when TRANBW[2:0] is changed is

TRANBW[2:0] = 1: transfer BW = 500 kHz
TRANBW[2:0] = 2: transfer BW = 1.0 MHz
TRANBW[2:0] = 3: transfer BW = 1.5 MHz
TRANBW[2:0] = 4: transfer BW = 2.0 MHz (default)
TRANBW[2:0] = 5: transfer BW = 2.5 MHz
TRANBW[2:0] = 6: transfer BW = 3.0 MHz
TRANBW[2:0] = 7: transfer BW = 3.5 MHz

Reducing the transfer bandwidth is commonly used in OTN applications. Never set TRANBW[2:0] = 0, because this makes the CDR open loop. Also, note that setting TRANBW[2:0] above 4 may cause a slight increase in jitter generation and potential jitter peaking.

LOSS OF SIGNAL (LOS) DETECTOR

The receiver front-end LOS detector circuit detects when the input signal level falls below a user-adjustable threshold.

There is typically 6 dB of electrical hysteresis on the LOS detector to prevent chatter on the LOS pin. This means that, if the input level drops below the programmed LOS threshold, causing the LOS pin to assert, the LOS pin is not deasserted until the input level has increased to 6 dB $(2\times)$ above the LOS threshold (see Figure 27).

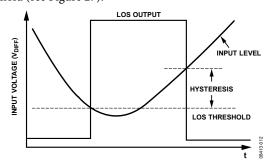

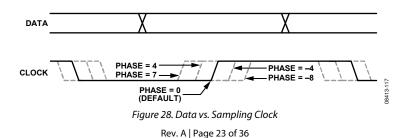

Figure 27. LOS Detector Hysteresis

The LOS detector and the slice level adjust can be used simultaneously on the ADN2915. Therefore, any offset added to the input signal by the slice adjust pins does not affect the LOS detector measurement of the absolute input level.

LOS Power-Down

The LOS, by default, is enabled and consumes power. The LOS is placed in a low power mode by setting the LOS PDN (CTRLB[3]) = 1 in Register 0x9.

LOS Threshold

The LOS threshold has a range between 0 mV and 128 mV and is set by writing the number of millivolts (mV) to the LOS_DATA register (0x36) followed by toggling the LOS_ENABLE bit in the LOS_CTRL register (Register 0x74) while LOS_ADDRESS is set to 1. The following is a procedure for writing the LOS threshold:

- 1. Write 0x21 to LOS_CTRL (Register 0x74).
- 2. Write the desired threshold in millivolts to LOS_DATA (Register 0x36).
- 3. Write 0x31 to LOS_CTRL (Register 0x74).
- 4. Write 0x21 to LOS_CTRL (Register 0x74).

The LOS threshold can be set to a value between 0 mV and 63 mV in 1 mV steps and 64 mV to 128 mV in 2 mV steps. In the lower range, all of the bits are active, giving 1 mV/LSB resolution, where Bit D0 is the LSB.

However, in the upper range, Bit D0 is disabled (that is, D0 = 0), making Bit D1 the new LSB and resulting in 2 mV/LSB resolution.

I²C Register LOS_CTRL contains the necessary address and write enable bits to program this LOS threshold.

Signal Strength Measurement

The LOS measures and digitizes the peak-to-peak amplitude of the received signal. A single shot measurement is taken by writing the following sequence of bytes to LOS_CTRL at I²C Address 0x74: 0x7, 0x17, 0x7. Upon LOS_ENABLE going low, the peak-to-peak amplitude in millivolts is loaded into LOS_DATA (Register 0x36). The contents of LOS_DATA change only when LOS_ENABLE (LOS_CTRL[4]) in Register 0x74 is toggled low-high-low while pointing to LOS_ADDRESS[2:0] (LOS_CTRL[2:0]) = 7.

PASSIVE EQUALIZER

A passive equalizer is available at the input to equalize large signals that have undergone distortion due to PCB traces, vias, and connectors. The adaptive EQ functions only at data rates greater than 5.5 Gbps. Therefore, at rates less than 5.5 Gbps, the EQ must be manually set.

The equalizer can be manually set through Register LA_EQ (Register 0x16). An adaptive loop is also available that optimizes the EQ setting based on characteristics of the received eye at the phase detector. If the channel is known in advance, manual set the EQ setting to obtain the best

performance; however, the adaptive EQ finds the best setting in most cases.

Table 22 indicates a typical EQ setting for several trace lengths. The values in Table 22 are based on measurements taken on a test board with simple FR-4 traces. Table 23 lists the typical maximum reach in inches of FR-4 of the EQ at several data rates. If a real channel includes lossy connectors or vias, the FR-4 reach length is lower. For any real-world system, it is highly recommended to test several EQ settings with the real channel to ensure best signal integrity.

Table 22. EQ Settings vs. Trace Length on FR-4

Trace Length (inches)	Typical EQ Setting
6	10
10	12
15	14
20 to 30	15

Table 23. Typical EQ Reach on FR-4 vs. Maximum Data Rates Supported

Maximum Data Rate (Gbps)	Typical EQ Reach on FR-4 (inches)
4	30
8	20
10	15
11	10

BYPASS

The bypass path connects the input signal directly to the digital logic inside the ADN2915. This is useful at lower data rates where the signal is large (therefore, the limiting amplifier is not needed, and power can be saved by deselecting the limiting amplifier) and unimpaired (therefore, the equalizer is not needed). The signal swing of the internal digital circuit is 600 mV p-p differential, the minimum signal amplitude that must be provided as the input in bypass mode.

In bypass mode, the internal 50 Ω termination resistors can be configured in one of two ways, either floated or tied to V_{CC} = 1.2 V (see Figure 33 and Table 26). By setting the RX_TERM_FLOAT bit (D7) in I²C Register LA_EQ (Register 0x16) to 1, these 50 Ω termination resistors are floated internal to the ADN2915 (see Figure 36). By setting RX_TERM_FLOAT bit (D7) to 0, these 50 Ω termination resistors are connected to V_{CC} = 1.2 V (see Figure 37). In both of these termination cases, the user must ensure a valid common-mode voltage on the input.

In the case where the termination is floated, the two 50 Ω resistors are purely a differential termination. The input must conform to the range of signals shown in Figure 39.

In the case of termination to 1.2 V V_{CC} power supply (see Figure 37 and Figure 38), the common-mode voltage is created by joint enterprise between the driver circuit and the 50 Ω resistors on the ADN2915. For example, the driver can be an open-drain switched current (see Figure 37), and the 50 Ω resistors return this current to V_{CC} . In Figure 37, the common-mode voltage is
