Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

700 MHz to 1050 MHz Quadrature Demodulator with Fractional-N PLL

Data Sheet

ADRF6807

FEATURES

- IQ demodulator with integrated fractional-N PLL
- LO frequency range: 700 MHz to 1050 MHz
- For the following specifications (LPEN = 0)/(LPEN = 1):
  - Input P1dB: 12.8 dBm/11.7 dBm
  - Input IP3: 26.7 dBm/24.0 dBm
  - Noise figure (DSB): 13.1 dB/12.4 dB
  - Voltage conversion gain: 1.0 dB/4.3 dB
- Quadrature demodulation accuracy
  - Phase accuracy: <0.5°
  - Amplitude accuracy: <0.1 dB
  - Baseband demodulation: 170 MHz/135 MHz, 3 dB bandwidth
- SPI serial interface for PLL programming
- 40-lead, 6 mm × 6 mm LFCSP

APPLICATIONS

- QAM/QPSK RF/IF demodulators
- Cellular W-CDMA/CDMA/CDMA2000
- Microwave point-to-(multi)point radios
- Broadband wireless and WiMAX

GENERAL DESCRIPTION

The ADRF6807 is a high dynamic range IQ demodulator with integrated phase-locked loop (PLL) and voltage controlled oscillator (VCO). The fractional-N PLL/synthesizer generates a frequency in the range of 2.8 GHz to 4.2 GHz. A programmable quadrature divider (divide ratio = 4) divides the output frequency of the VCO down to the required local oscillator (LO) frequency to drive the mixers in quadrature. Additionally, an output divider (divide ratio = 4 to 8) generates a divided-down VCO signal for external use.

The PLL reference input is supported from 9 MHz to 160 MHz. The phase detector output controls a charge pump whose output is integrated in an off-chip loop filter. The loop filter output is then applied to an integrated VCO.

The IQ demodulator mixes the differential RF input with the complex LO derived from the quadrature divider. The differential I and Q output paths have excellent quadrature accuracy and can handle baseband signaling or complex IF up to 120 MHz.

A reduced power mode of operation is also provided by programming the serial interface registers to reduce current consumption, with slightly degraded input linearity and output current drive.

The ADRF6807 is fabricated using an advanced silicon-germanium BiCMOS process. It is available in a 40-lead, exposed paddle, RoHS-compliant, 6 mm × 6 mm LFCSP package. Performance is specified over the −40°C to +85°C temperature range.

SPECIFICATIONS

V_{S1} (V_{VCCBB} and V_{VCCRF}) = 5 V, and V_{S2} (V_{VCC1}, V_{VCC2}, and V_{VCCLO}) = 3.3 V; ambient temperature (T_A) = 25°C; f_{REF} = 26 MHz, f_{LO} = 900 MHz, f_{BB} = 4.5 MHz, R_{LOAD} = 450 Ω differential, RF port driven from a 1:2 balun to step up the 50 Ω source impedance to match the 100 Ω differential RF input port impedance, all register and PLL settings use the recommended values shown in the Register Structure section, unless otherwise noted.

Table 1.

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
FREQUENCY RANGE		700		1050	MHz
RF INPUT at 900 MHz	RFIP, RFIN pins				
Input Return Loss	Relative to 100 Ω		−18		dB
Input P1dB	LPEN = 0 (standard power mode)		12.8		dBm
	LPEN = 1 (low power mode)		11.7		dBm
Second-Order Input Intercept (IIP2)	LPEN = 0; −5 dBm each tone		>65		dBm
	LPEN = 1; −5 dBm each tone		>65		dBm
Third-Order Input Intercept (IIP3)	LPEN = 0; −5 dBm each tone		26.7		dBm
	LPEN = 1; −5 dBm each tone		24.0		dBm
Noise Figure	Double sideband from RF to either I or Q output; LPEN = 0		13.1		dB
	Double sideband from RF to either I or Q output; LPEN = 1		12.4		dB
	With a −5 dBm interferer 5 MHz away		16		dB
LO-to-RF Leakage	At 1×LO frequency, 100 Ω termination at the RF port		−73		dBm
I/Q BASEBAND OUTPUTS	IBBP, IBBN, QBBP, QBBN pins				
Voltage Conversion Gain	450 Ω differential load across IBBP, IBBN (or QBBP, QBBN); LPEN = 0		1		dB
	450 Ω differential load across IBBP, IBBN (or QBBP, QBBN); LPEN = 1		4.3		dB
Demodulation Bandwidth	1 V p-p signal 3 dB bandwidth; LPEN = 0		170		MHz
	1 V p-p signal 3 dB bandwidth; LPEN = 1		135		MHz
Quadrature Phase Error			0.35		Degrees
I/Q Amplitude Imbalance			0.05		dB
Output DC Offset (Differential)			±8		mV
Output Common-Mode Reference	VOCM applied input voltage	1.55	1.65	1.75	V
Common-Mode Offset	$\lvert(V_{IBBP} + V_{IBBN})/2 - V_{VOCM}\rvert$, $\lvert(V_{QBBP} + V_{QBBN})/2 - V_{VOCM}\rvert$		25		mV
Gain Flatness	Any 5 MHz		0.2		dB p-p
Maximum Output Swing	Differential 450 Ω load		3		V p-p
	Differential 200 Ω load		2.4		V p-p
Maximum Output Current	Each pin		6		mA p-p
LO INPUT/OUTPUT	LOP, LON				
Output Level (LPEN = 0)	Into a differential 50 Ω load, LO buffer enabled (output frequency = 800 MHz)		1		dBm
Output Level (LPEN = 1)	Into a differential 50 Ω load, LO buffer enabled (output frequency = 800 MHz)		−0.75		dBm
Input Level	Externally applied 2×LO, PLL disabled		0		dBm
Input Impedance	Externally applied 2×LO, PLL disabled		50		Ω

ABSOLUTE MAXIMUM RATINGS

Table 3.

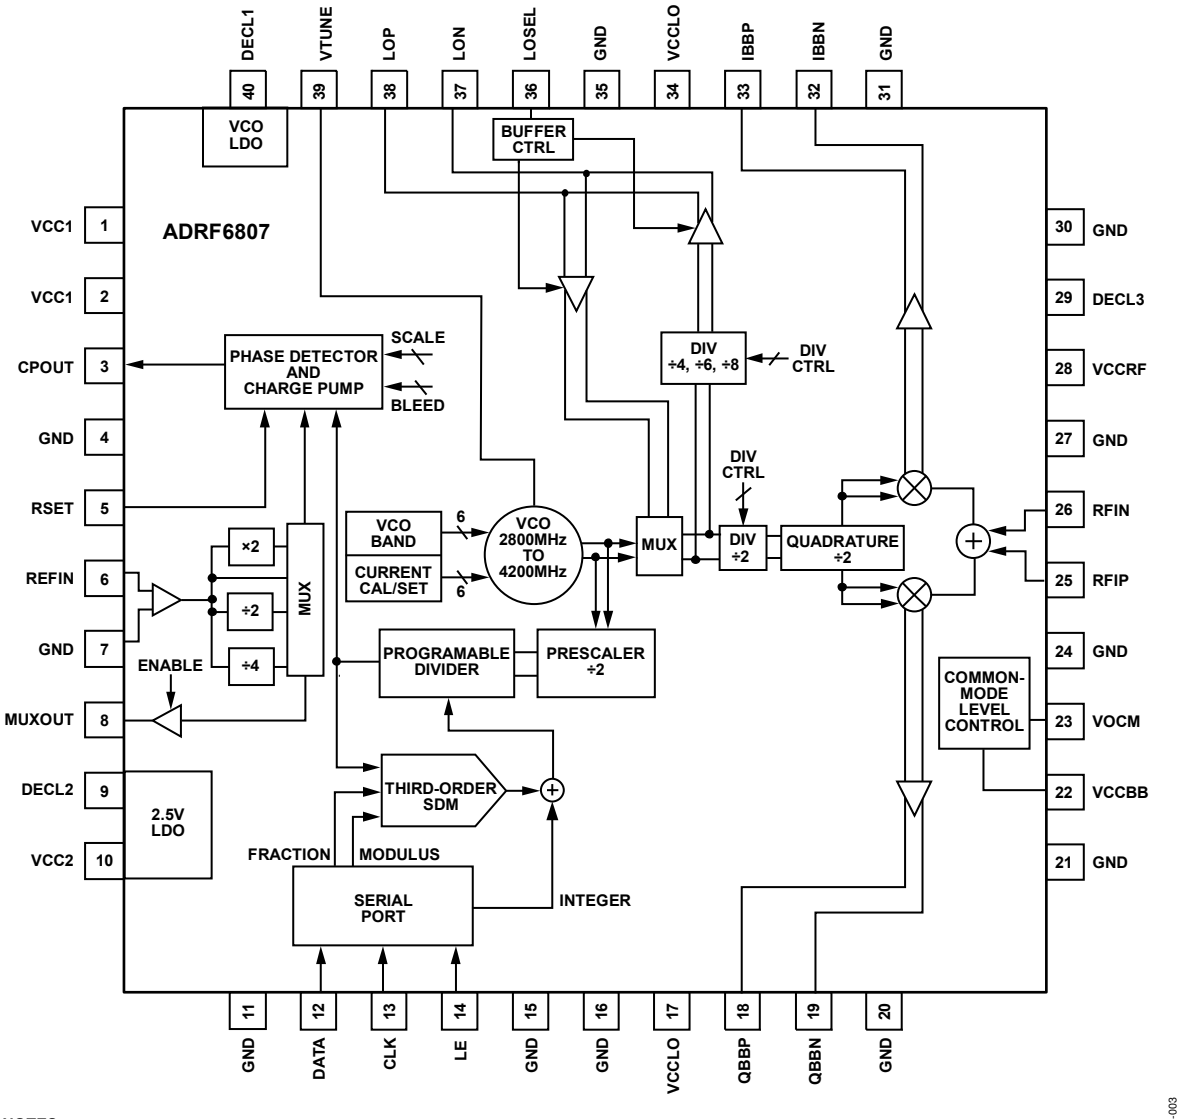
Parameter	Rating
Supply Voltage, VCCBB and VCCRF (V_{S1})	−0.5 V to +5.5 V
Supply Voltage, VCC1, VCC2, and VCCLO (V_{S2})	−0.5 V to +3.6 V
Digital I/O, CLK, DATA, and LE	−0.3 V to +3.6 V
RFIP and RFIN (Each Pin AC-Coupled)	13 dBm
θ_{JA} (Exposed Paddle Soldered Down)	30°C/W
Maximum Junction Temperature	150°C
Operating Temperature Range	−40°C to +85°C
Storage Temperature Range	−65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS



NOTES
1. THE EXPOSED PADDLE SHOULD BE SOLDERED TO A LOW IMPEDANCE GROUND PLANE.

Figure 3. Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1, 2	VCC1	The 3.3 V Power Supply for VCO and PLL.
3	CPOUT	Charge Pump Output Pin. Connect this pin to VTUNE through the loop filter.
4, 7, 11, 15, 16, 20, 21, 24, 27, 30, 31, 35	GND	Ground. Connect these pins to a low impedance ground plane.
5	RSET	Charge Pump Current. The nominal charge pump current can be set to 250 µA, 500 µA, 750 µA, or 1 mA using DB10 and DB11 of Register 4 and by setting DB18 to 0 (internal reference current). In this mode, no external R_{SET} is required. If DB18 is set to 1, the four nominal charge pump currents ($I_{NOMINAL}$) can be externally tweaked according to the following equation where the resulting value is in units of ohms. $R_{SET} = \left[\frac{217.4 \times I_{CP}}{I_{NOMINAL}}\right] - 37.8$

Pin No.	Mnemonic	Description
6	REFIN	Reference Input. Nominal input level is 1 V p-p. Input range is 9 MHz to 160 MHz.
8	MUXOUT	Multiplexer Output. This output can be programmed to provide the reference output signal or the lock detect signal. The output is selected by programming the appropriate register.
9	DECL2	Connect a 0.1 µF capacitor between this pin and ground.
10	VCC2	3.3 V Power Supply for 2.5 V LDO.
12	DATA	Serial Data Input. The serial data is loaded MSB first with the three LSBs being the control bits.
13	CLK	Serial Clock Input. This serial clock is used to clock in the serial data to the registers. The data is latched into the 24-bit shift register on the CLK rising edge. Maximum clock frequency is 20 MHz.
14	LE	Load Enable. When the LE input pin goes high, the data stored in the shift registers is loaded into one of the six registers, the relevant latch being selected by the first three control bits of the 24-bit word.
17, 34	VCCLO	3.3 V Power Supply for LO Path Blocks.
18, 19	QBBP, QBBN	Demodulator Q-Channel Differential Baseband Outputs (Differential Output Impedance of 28 Ω).
22	VCCBB	5 V Power Supply for Demodulator Blocks.
23	VOCM	Baseband Common-Mode Reference Input; 1.65 V Nominal. It sets the dc common-mode level of the IBBx and QBBx outputs.
25, 26	RFIP, RFIN	Differential 100 Ω, Internally Biased RF Inputs. These pins must be ac-coupled.
28	VCCRF	5 V Power Supply for Demodulator Blocks.
29	DECL3	Connect a 2.2 µF capacitor between this pin and ground.
32, 33	IBBN, IBBP	Demodulator I-Channel Differential Baseband Outputs (Differential Output Impedance of 28 Ω).
36	LOSEL	LO Select. Connect this pin to ground for the simplest operation and to completely control the LO path and input/output direction from the register programming of the SPI. For additional control without register reprogramming, this input pin can determine whether the LOP and LON pins operate as inputs or outputs. LOP and LON become inputs if the LOSEL pin is set low, the LDRV bit of Register 5 is set low, and the LXL bit of Register 5 is set high. The externally applied LO drive must be at M×LO frequency (where M corresponds to the main LO divider setting). LON and LOP become outputs when LOSEL is high or if the LDRV bit of Register 5 (DB3) is set high and the LXL bit of Register 5 (DB4) is set to low. The output frequency is controlled by the LO output divider bits in Register 7. This pin should not be left floating.
37, 38	LON, LOP	Local Oscillator Input/Output (Differential Output Impedance of 28 Ω). When these pins are used as output pins, a differential frequency divided version of the internal VCO is available on these pins. When the internal LO generation is disabled, an external M×LO frequency signal can be applied to these pins, where M corresponds to the main divider setting.
39	VTUNE	VCO Control Voltage Input. This pin is driven by the output of the loop filter. The nominal input voltage range on this pin is 1.0 V to 2.8 V.
40	DECL1	Connect a 10 µF capacitor between this pin and ground as close to the device as possible because this pin serves as the VCO supply and loop filter reference.
	EP	Exposed Paddle. The exposed paddle should be soldered to a low impedance ground plane.

TYPICAL PERFORMANCE CHARACTERISTICS

V_{S1} = 5 V, V_{S2} = 3.3 V, T_A = 25°C, RF input balun loss is de-embedded, unless otherwise noted. LO = 700 MHz to 1050 MHz; Mini-Circuits ADTL2-18 balun on RF inputs.

CIRCUIT DESCRIPTION

The ADRF6807 integrates a high performance IQ demodulator with a state-of-the-art fractional-N PLL. The PLL also integrates a low noise VCO. The SPI port allows the user to control the fractional-N PLL functions, the demodulator LO divider functions, and optimization functions, as well as allowing for an externally applied LO.

The ADRF6807 uses a high performance mixer core that results in an exceptional input IP3 and input P1dB, with a very low output noise floor for excellent dynamic range.

LO QUADRATURE DRIVE

A signal at 2× the desired mixer LO frequency is delivered to a divide-by-2 quadrature phase splitter followed by limiting amplifiers, which then drive the I and Q mixers, respectively.

V-TO-I CONVERTER

The differential RF input signal is applied to a V-to-I converter that converts the differential input voltage to output currents. The V-to-I converter provides a differential 100 Ω input impedance. The V-to-I bias current can be reduced by putting the device in low power mode (setting LPEN = 1 by setting Register 5, DB5 = 1). Generally with LPEN = 1, input IP3 and input P1dB degrade, but the noise figure is slightly better. Overall, the dynamic range is reduced by setting LPEN = 1.

MIXERS

The ADRF6807 has two double-balanced mixers: one for the in-phase channel (I channel) and one for the quadrature channel (Q channel). These mixers are based on the Gilbert cell design of four cross-connected transistors. The output currents from the two mixers are summed together in the resistive loads that then feed into the subsequent emitter follower buffers. When the part is put into its low power mode (LPEN = 1), the mixer core load resistors are increased, which does increase the gain by roughly 3 dB; however, as previously stated in the V-to-I Converter section, the overall dynamic range does decrease slightly.

EMITTER FOLLOWER BUFFERS

The output emitter followers drive the differential I and Q signals off chip. The output impedance is set by on-chip 14 Ω series resistors that yield a 28 Ω differential output impedance for each baseband port. The fixed output impedance forms a voltage divider with the load impedance that reduces the effective gain. For example, a 500 Ω differential load has ~0.5 dB lower effective gain than a high (10 kΩ) differential load impedance.

The common-mode dc output levels of the emitter follower outputs are set by the voltage applied to the VOCM pin. The VOCM pin must be driven with a voltage (typically 1.65 V) for the emitter follower buffers to function. If the VOCM pin is left open, the emitter follower outputs do not bias up properly.

BIAS CIRCUITRY

There are several band gap reference circuits and two low dropout regulators (LDOs) in the ADRF6807 that generate the reference currents and voltages used by different sections. One of the LDOs is the 2.5V_LDO, which is always active and provides the 2.5 V supply rail used by the internal digital logic blocks. The 2.5V_LDO output is connected to the DECL2 pin (Pin 9) for the user to provide external decoupling. The other LDO is the VCO_LDO, which acts as the positive supply rail for the internal VCO. The VCO_LDO output is connected to the DECL1 pin (Pin 40) for the user to provide external decoupling. The VCO_LDO can be powered down by setting Register 6, DB18 = 0, which allows the user to save power when not using the VCO. Additionally, the bias current for the mixer V-to-I stage, which drives the mixer core, can be reduced by putting the device in low power mode (setting LPEN = 1 by setting Register 5, DB5 = 1).

REGISTER STRUCTURE

The ADRF6807 provides access to its many programmable features through a 3-wire SPI control interface that is used to program the seven internal registers. The minimum delay and hold times are shown in the timing diagram (see Figure 2). The SPI provides digital control of the internal PLL/VCO as well as several other features related to the demodulator core, on-chip referencing, and available system monitoring functions. The MUXOUT pin provides a convenient, single-pin monitor output signal that can be used to deliver a PLL lock-detect signal or an internal voltage proportional to the local junction temperature.

Note that internal calibration for the PLL must run when the ADRF6807 is initialized at a given frequency. This calibration is run automatically whenever Register 0, Register 1, or Register 2 is programmed. Because the other registers affect PLL performance, Register 0, Register 1, and Register 2 must always be programmed last. For ease of use, starting the initial programming with Register 7 and then programming the registers in descending order ending with Register 0 is recommended. Once the PLL and other settings are programmed, the user can change the PLL frequency simply by programming Register 0, Register 1, or Register 2 as necessary.

Figure 33. Integer Divide Control Register (R0)

Register 0—Integer Divide Control

With R0[2:0] set to 000, the on-chip integer divide control register is programmed as shown in Figure 33. The internal VCO frequency (f_{VCO}) equation is

$$f_{VCO} = f_{PFD} \times (INT + (FRAC/MOD)) \times 2 \quad (1)$$

where:

f_{VCO} is the output frequency of the internal VCO.
INT is the preset integer divide ratio value (21 to 123 for integer mode, 24 to 119 for fractional mode).
FRAC is the preset fractional divider ratio value (0 to MOD − 1).
MOD is the preset fractional modulus (1 to 2047).

The integer divide ratio sets the INT value in Equation 1. The INT, FRAC, and MOD values make it possible to generate output frequencies that are spaced by fractions of the PFD frequency.

Note that the demodulator LO frequency is given by $f_{LO} = f_{VCO}/M$, where M is the programmed LO main divider (see Table 5).

Divide Mode

Divide mode determines whether fractional mode or integer mode is used. In integer mode, the VCO output frequency, f_{VCO}, is calculated by

$$f_{VCO} = f_{PFD} \times (INT) \times 2 \quad (2)$$

Register 1—Modulus Divide Control

With R1[2:0] set to 001, the on-chip modulus divide control register is programmed as shown in Figure 34. The MOD value is the preset fractional modulus ranging from 1 to 2047.

Figure 36. Σ-Δ Modulator Dither Control Register (R3)

Register 4—Charge Pump, PFD, and Reference Path Control

With R4[2:0] set to 100, the on-chip charge pump, PFD, and reference path control register is programmed as shown in Figure 37.

The charge pump current is controlled by the base charge pump current ($I_{CP, BASE}$), and the value of the charge pump current multiplier ($I_{CP, MULT}$).

The base charge pump current can be set using an internal or external resistor (according to DB18 of Register 4). When using an external resistor, the value of $I_{CP, BASE}$ can be varied according to

$$R_{SET}\ [\Omega] = \left[\frac{217.4 \times I_{CP, BASE}}{250}\right] - 37.8$$

The actual charge pump current can be programmed to be a multiple (1, 2, 3, or 4) of the charge pump base current. The multiplying value ($I_{CP, MULT}$) is equal to 1 plus the value of the DB11 and DB10 bits in Register 4.

The PFD phase offset multiplier ($\theta_{PFD, OFS}$), which is set by Bit DB16 to Bit DB12 of Register 4, causes the PLL to lock with a nominally fixed phase offset between the PFD reference signal and the divided-down VCO signal. This phase offset is used to linearize the PFD-CP transfer function and can improve fractional spurs. The magnitude of the phase offset is determined by

$$|\Delta\Phi|[\text{deg}] = 22.5\frac{\theta_{PFD, OFS}}{I_{CP, MULT}}$$

Finally, the phase offset can be either positive or negative, depending on the value of the DB17 bit in Register 4.

The reference frequency applied to the PFD can be manipulated using the internal reference path source. The external reference frequency applied can be internally scaled in frequency by 2×, 1×, 0.5×, or 0.25×. This allows a broader range of reference frequency selections while keeping the reference frequency applied to the PFD within an acceptable range.

The ADRF6807 also provides a MUXOUT pin that can be programmed to output a selection of several internal signals. The default mode provides a lock-detect output that allows users to verify when the PLL has locked to the target frequency. In addition, several other internal signals can be routed to the MUXOUT pin as shown in Figure 37.

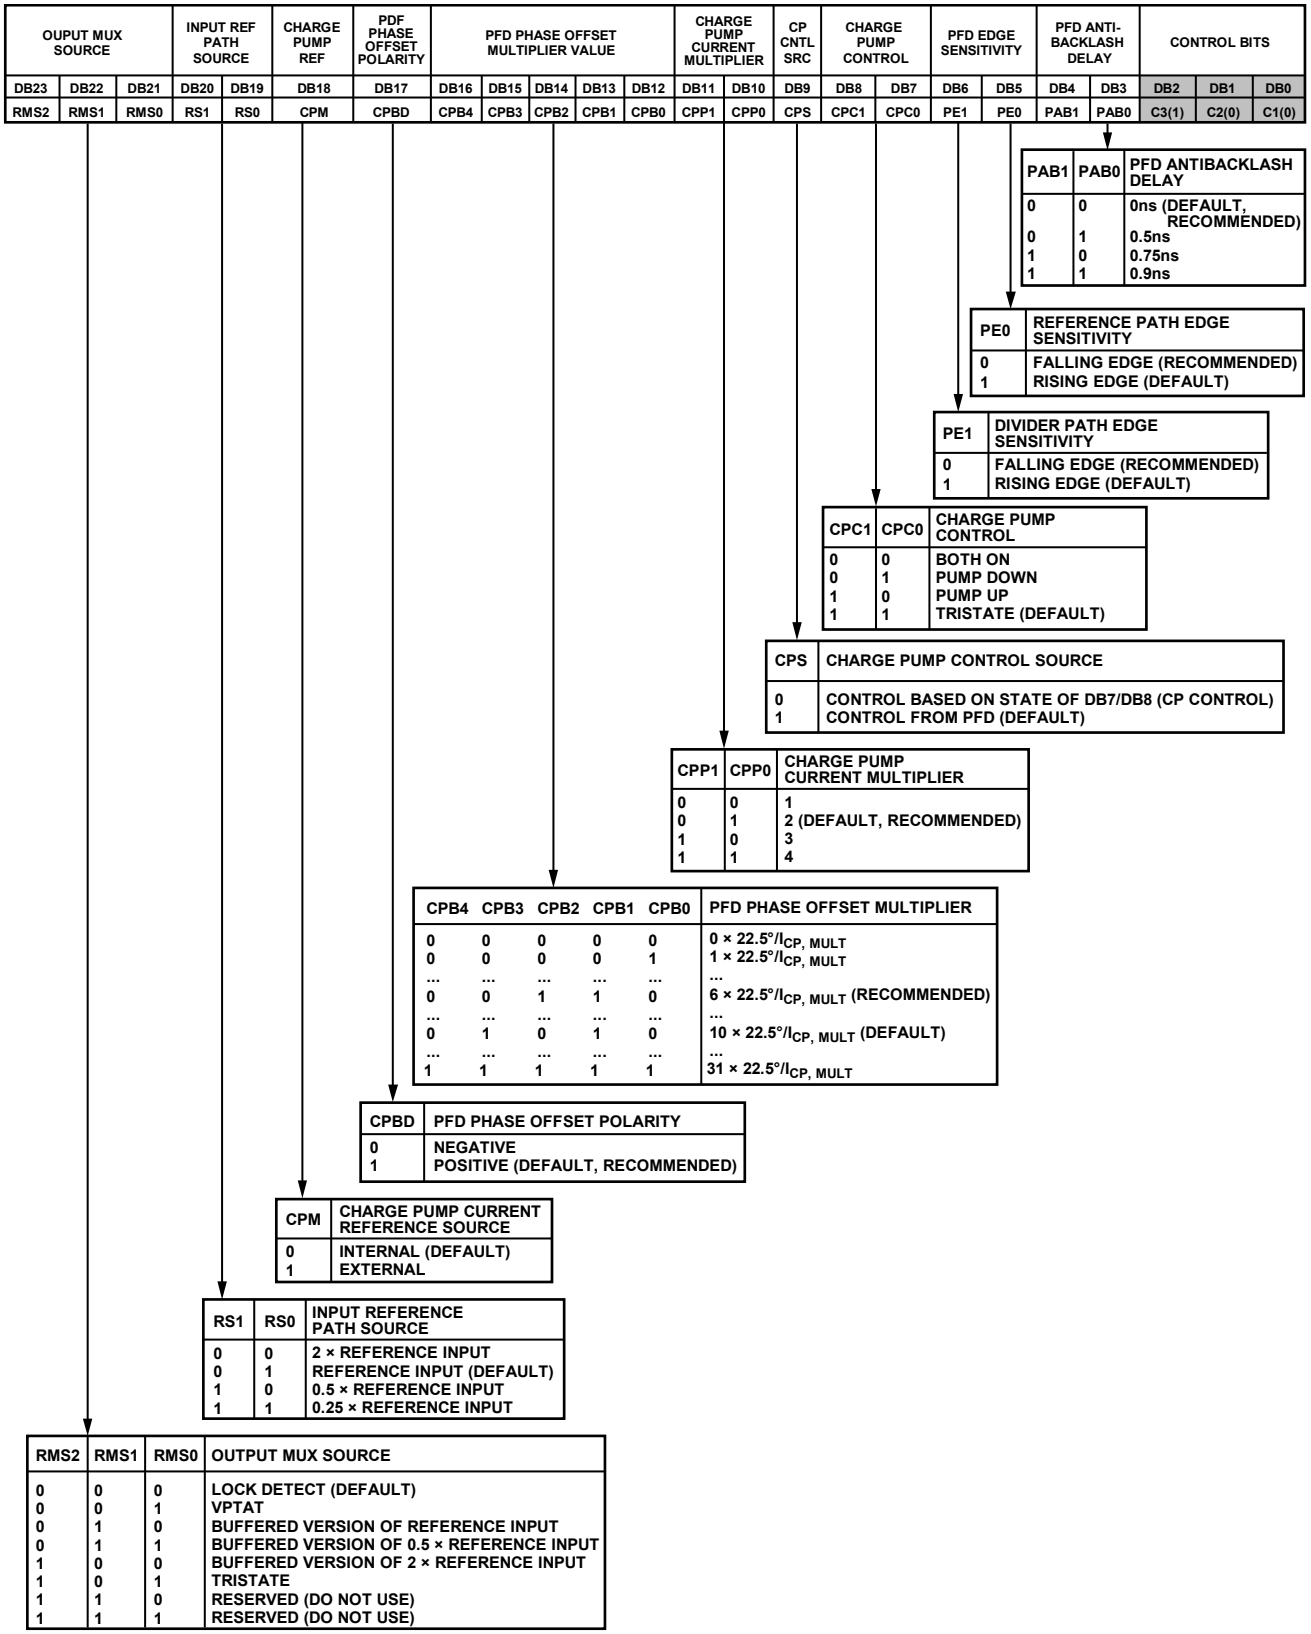

Figure 37. Charge Pump, PFD, and Reference Path Control Register (R4)

Register 5—LO Path and Demodulator Control

With R5[DB5] = 1, the ADRF6807 is in a lower power operating mode. The device is still fully functional in this lower power mode, but the mixer performance is shifted (see the Typical Performance Characteristics section for details on performance differences). Setting R5[DB5] = 0 causes the ADRF6807 mixer stage to run at a higher current, thereby achieving a higher IIP3.

Register 5 also controls whether the LOIP and LOIN pins act as an input or output and whether the output driver is enabled as detailed in Figure 38.

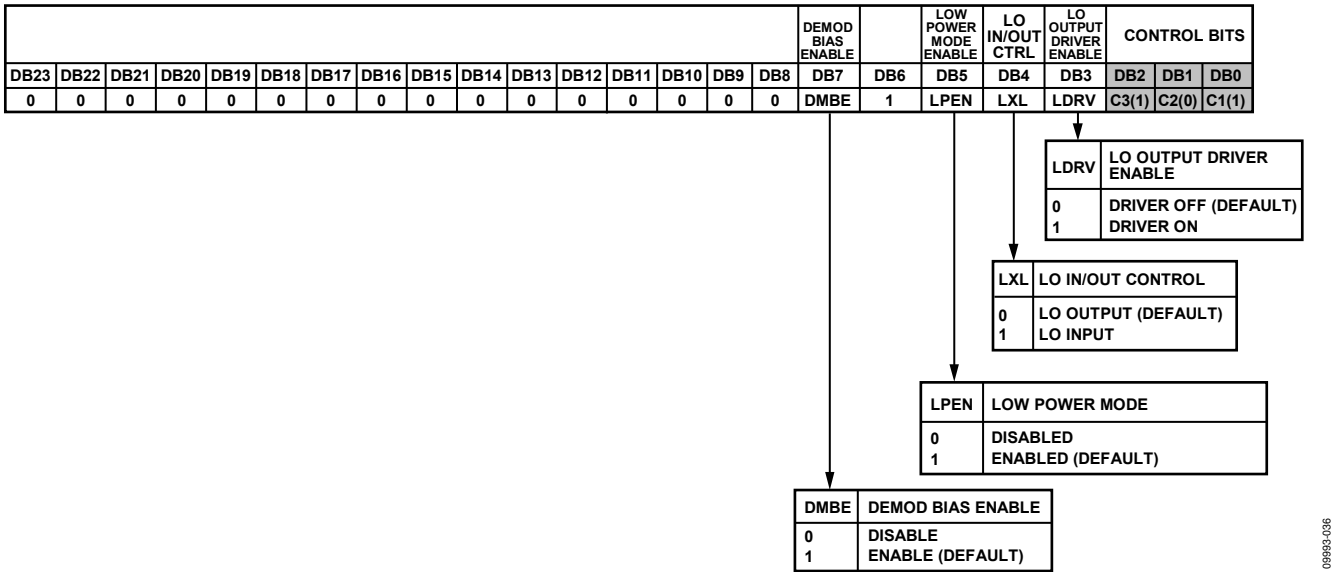

Figure 38. LO Path and Demodulator Control Register (R5)

Register 6—VCO Control and Enables

With R6[2:0] set to 110, the VCO control and enables register is programmed as shown in Figure 39.

VCO band selection is normally selected based on an internal BANDCAL calibration; however, the VCO band can be selected directly using Register 6. The VCO BS SRC determines whether the BANDCAL calibration determines the optimum VCO tuning band or if the external SPI interface is used to select the VCO tuning band based on the value of the VCO band select.

The VCO amplitude can be controlled through Register 6. The VCO amplitude setting can be controlled between 0 and 31 decimal, with a default value of 24.

The internal VCO can be disabled using Register 6. The internal VCO LDO can be disabled if an external clean 3.0 V supply is available.

The internal charge pump can be disabled through Register 6. Normally, the charge pump is enabled.

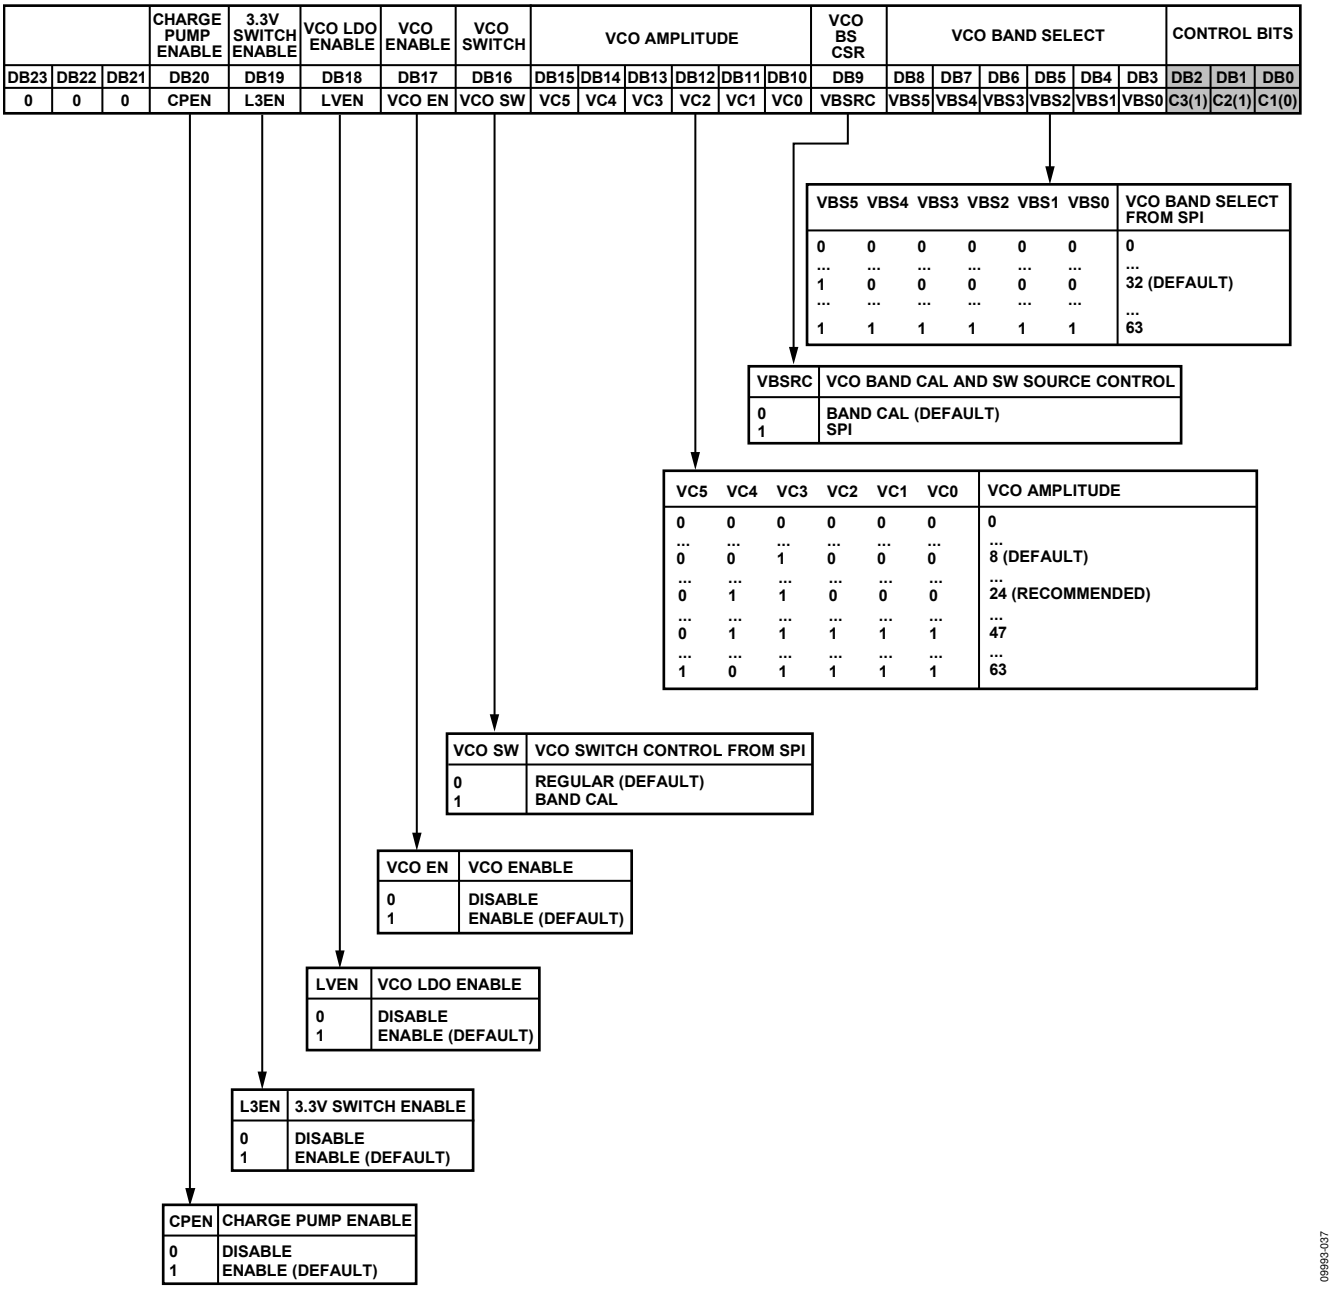

Figure 39. VCO Control and Enables (R6)

Register 7—LO Divider Control

Register 7 controls the LO path main divider settings as well as the LO output path divider setting. Table 5 indicates how to program this register to achieve the specified divider mode.

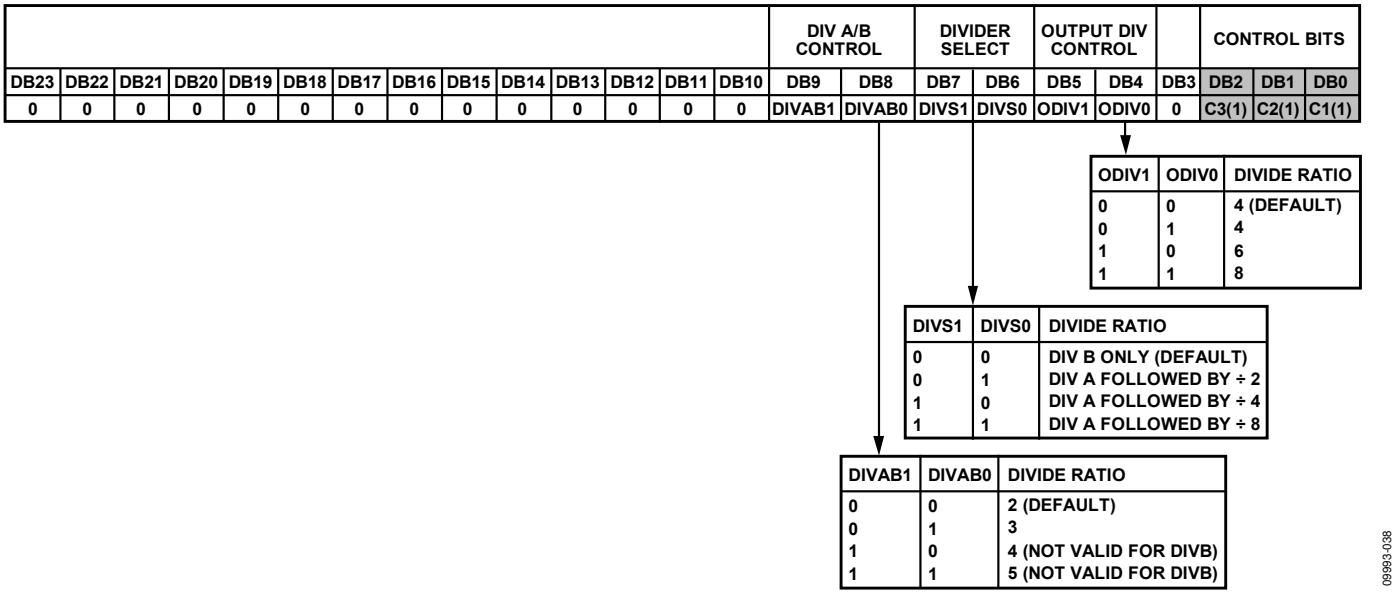

Figure 40. LO Divider Control Register (R7)

LO DIVIDER PROGRAMMING

Table 5. Main Divider (Only Divide Ratios and Combinations Specified Are Guaranteed)

f_{LO} (MHz)	LO Divider Ratio	f_{VCO} (MHz)	Divider Cascade			Register 7, DB[9:6]
			Divide-by-2 to Divide-by-5	Divide-by-2, Divide-by-4, or Divide-by-8	Quadrature Divide-by-2	
700 to 1050	4	2800 to 4200	2	Not used	2	00 00

Table 6. Output Divider

f_{LO} Output (MHz)	Output Divider Ratio	f_{VCO} (MHz)	Register 7, DB[5:4]
350 to 525	8	2800 to 4200	11
466.67 to 700	6	2800 to 4200	10
700 to 1050	4	2800 to 4200	01

PROGRAMMING EXAMPLE

For example, internal LO frequency = 700 MHz. This can be accomplished with the VCO/PLL frequency at 2800 MHz and an LO divide ratio of 4. The choice of output divider ratio of 8 gives an output frequency of 350 MHz. To achieve this combination, a binary code of 00 00 11 should be programmed into DB[9:4] of Register 7.

APPLICATIONS INFORMATION

BASIC CONNECTIONS

The basic circuit connections for a typical ADRF6807 application are shown in Figure 41.

SUPPLY CONNECTIONS

The ADRF6807 has several supply connections and on-board regulated reference voltages that should be bypassed to ground using low inductance bypass capacitors located in close proximity to the supply and reference pins of the ADRF6807. Specifically, Pin 1, Pin 2, Pin 9, Pin 10, Pin 17, Pin 22, Pin 23, Pin 28, Pin 29, Pin 34, and Pin 40 should be bypassed to ground using individual bypass capacitors. Pin 40 is the decoupling pin for the on-board VCO LDO, and for best phase noise performance, several bypass capacitors ranging from 100 pF to 10 µF may help to improve phase noise performance. For additional details on bypassing the supply nodes, see the evaluation board schematic in Figure 43.

SYNTHESIZER CONNECTIONS

The ADRF6807 includes an on-board VCO and PLL for LO synthesis. An external reference must be applied for the PLL to operate. A 1 V p-p nominal external reference must be applied to Pin 6 through an ac coupling capacitor. The reference is compared to an internally divided version of the VCO output frequency to create a charge pump error current to control and lock the VCO. The charge pump output current is filtered and converted to a control voltage through the external loop filter that is then applied to the VTUNE pin (Pin 39). ADIsimPLL™ can be a helpful tool when designing the external charge pump loop filter. The typical Kv of the VCO, the charge pump output current magnitude, and PFD frequency should all be considered when designing the loop filter. The charge pump current magnitude can be set internally or with an external RSET resistor connected to Pin 5 and ground, along with the internal digital settings applied to the PLL (see the Register 4—Charge Pump, PFD, and Reference Path Control section for more details).

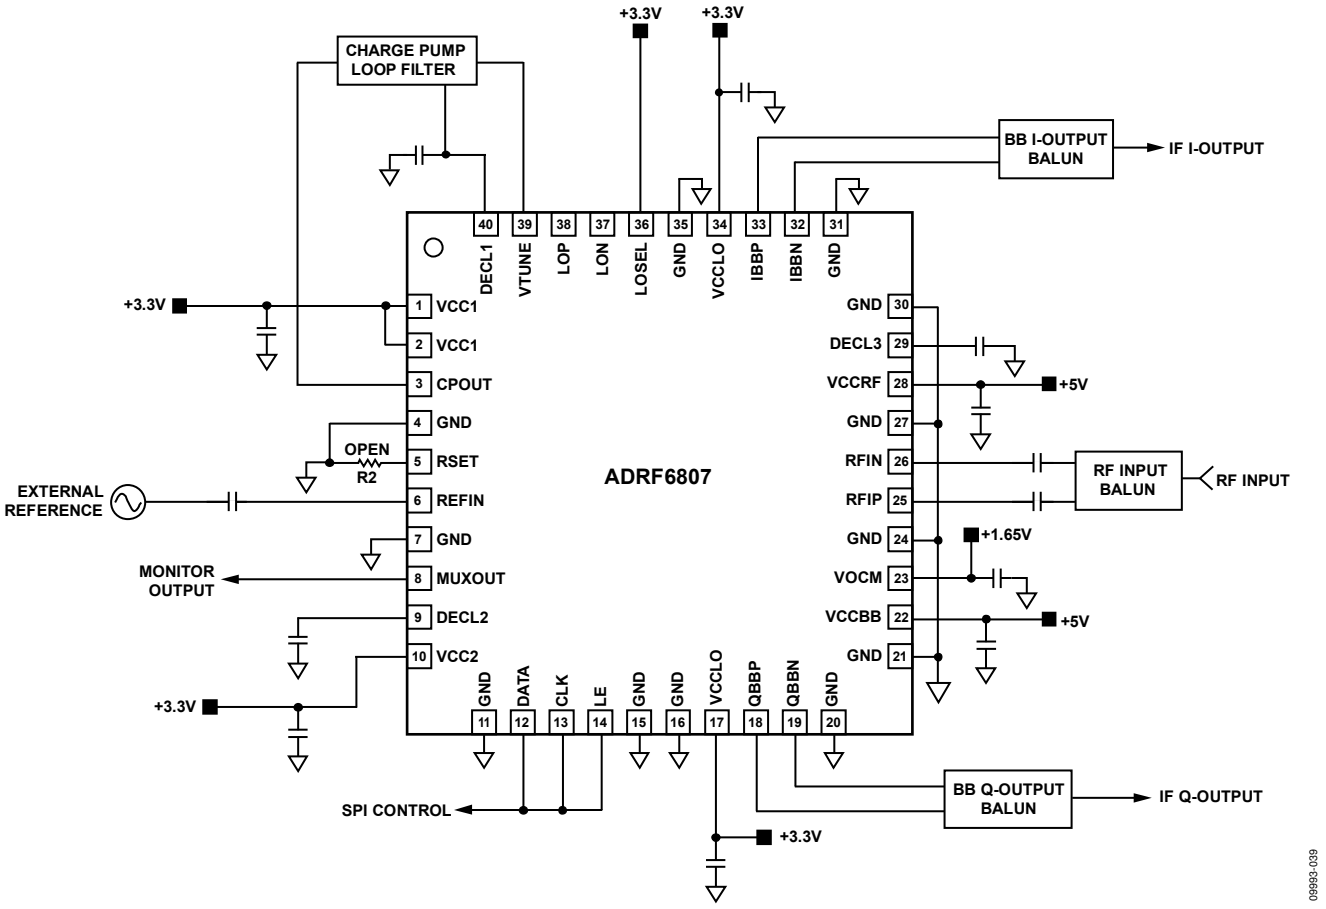

Figure 41. Basic Connections

I/Q OUTPUT CONNECTIONS

The ADRF6807 has I and Q baseband outputs. Each output stage consists of emitter follower output transistors with a low differential impedance of 28 Ω and can source up to 12 mA p-p differentially. A Mini-Circuits TCM9-1+ balun is used to transform a single-ended 50 Ω load impedance into a nominal 450 Ω differential impedance.

RF INPUT CONNECTIONS

The ADRF6807 uses a Mini-Circuits ADTL2-18+ balun with a 2:1 impedance ratio to transform a single-ended 50 Ω impedance into a differential 100 Ω impedance. Coupling capacitors whose impedance is small compared to 100 Ω at the frequency of operation are used to isolate the dc bias points of the RF input stage.

CHARGE PUMP/VTUNE CONNECTIONS

The ADRF6807 uses a loop filter to create the VTUNE voltage for the internal VCO. The loop filter in its simplest form is an integrating capacitor. It converts the current mode error signal coming out of the CPOUT pin into a voltage to control the VCO via the VTUNE voltage. The stock filter on the evaluation board has a bandwidth of 67 kHz. The loop filter contains five components, three capacitors, and two resistors. Changing the values of these components changes the bandwidth of the loop filter.

LO SELECT INTERFACE

The ADRF6807 has the option of either monitoring a scaled version of the internally generated LO (LOSEL pin driven high at 3.3 V) or providing an external LO source (LOSEL pin driven low to ground, the LDRV bit in Register 5 set low, and the LXL bit in Register 5 set high). See the Pin Configuration and Function Descriptions section for full operation details.

EXTERNAL LO INTERFACE

The ADRF6807 provides the option to use an external signal source for the LO into the IQ demodulating mixer core. It is important to note that the applied LO signal is divided down by a divider (programmable to between 4 and 80) prior to the actual IQ demodulating mixer core. The divider is determined by the register settings in the LO path and mixer control register (see the Register 5—LO Path and Demodulator Control section). The LO input pins (Pin 37 and Pin 38) present a broadband differential 50 Ω input impedance. The LOP and LON input pins must be ac-coupled. This is achieved on the evaluation board via a Mini-Circuits TC1-1-13+ balun with a 1:1 impedance ratio. When not in use, the LOP and LON pins can be left unconnected.

SETTING THE FREQUENCY OF THE PLL

The frequency of the VCO/PLL, once locked, is governed by the values programmed into the PLL registers, as follows:

$$f_{PLL} = f_{PFD} \times 2 \times (INT + FRAC/MOD)$$

where:
f_{PLL} is the frequency at the VCO when the loop is locked.
f_{PFD} is the frequency at the input of the phase frequency detector.
INT is the integer divide ratio programmed into Register 0.
FRAC is the fractional value programmed into Register 2.
MOD is the modulus divide ratio programmed into Register 1.

The practical lower limit of the reference input frequency is determined by the combination of the desired f_{PLL} and the maximum programmable integer divide ratio of 119 and reference input frequency multiplier of 2. For a maximum f_{PLL} of 4200 MHz,

$$f_{REF} > \sim f_{PLL}/(f_{PFD} \times 2 \times 2), \text{ or } 8.8 \text{ MHz}$$

A lock detect signal is available as one of the selectable outputs through the MUXOUT pin, with logic high signifying that the loop is locked.

REGISTER PROGRAMMING

Because Register 6 controls the powering of the VCO and charge pump, it must be programmed once before programming the PLL frequency (Register 0, Register 1, and Register 2).

The registers should be programmed starting with the highest register (Register 7) first and then sequentially down to Register 0 last. When Register 0, Register 1, or Register 2 is programmed, an internal VCO calibration is initiated that must execute when the other registers are set. Therefore, the order must be Register 7, Register 6, Register 5, Register 4, Register 3, Register 2, Register 1, and then Register 0. Whenever Register 0, Register 1, or Register 2 is written to, it initializes the VCO calibration (even if the value in these registers does not change). After the device has been powered up and the registers configured for the desired mode of operation, only Register 0, Register 1, or Register 2 must be programmed to change the LO frequency.

If none of the register values are changing from their defaults, there is no need to program them.

EVM MEASUREMENTS

EVM is a measure used to quantify the performance of a digital radio transmitter or receiver. A signal received by a receiver has all constellation points at their ideal locations; however, various imperfections in the implementation (such as magnitude imbalance, noise floor, and phase imbalance) cause the actual constellation points to deviate from their ideal locations.

In general, a demodulator exhibits three distinct EVM limitations vs. received input signal power. As signal power increases, the distortion components increase. At large signal levels, where the distortion components due to the harmonic nonlinearities in the device are falling in-band, EVM degrades as signal levels increase. At medium signal levels, where the demodulator behaves in a linear manner and the signal is well above any notable noise contributions, the EVM has a tendency to reach an optimal level determined dominantly by either quadrature accuracy and I/Q gain match of the demodulator or the precision of the test equipment. As signal levels decrease, such that the noise is a major contribution, the EVM performance vs. the signal level exhibits a decibel-for-decibel degradation with decreasing signal level. At lower signal levels, where noise proves to be the dominant limitation, the decibel EVM proves to be directly proportional to the SNR.

The basic test setup for testing the EVM of the ADRF6807 consisted of an Agilent E4438C, which was used as a signal source. The 900 MHz modulated signal was driven single ended into the RFIN SMA connector of the ADRF6807 evaluation board. The IQ baseband outputs were taken differentially into a pair of AD8130 difference amplifiers to convert the differential signals to single ended. The output impedance that the ADRF6807 drove was set to 450 Ω differential. The single-ended I and Q signals were then sampled by an Agilent DSO7104B oscilloscope. The Agilent 89400 VSA software was used to calculate the EVM of the signal. The signal source that was used for the reference input was a Wenzel 100 MHz quarts oscillator set at an amplitude of 1 V p-p. The reference path was set to a divide-by-four, thus making the PFD frequency 25 MHz.

Figure 42 shows the excellent EVM of the ADRF6807 being better than −40 dB over an RF input range of about 40 dB for a 4 QAM modulated signal, at a 5 MHz symbol rate and at a 0 Hz IF. The roll-off, or alpha, of the pulse shaping filter was set to 0.35. The reported RF input power is the power integrated across the bandwidth of

$$BW = (1 + \alpha) \times (Symbol\ Rate)$$

EVM was tested for both power modes: low power mode disabled (LPEN = 0) and low power mode enabled (LPEN = 1). When the low power mode is enabled, the EVM is better at lower RF input signal levels due to less noise while running in the low power mode.

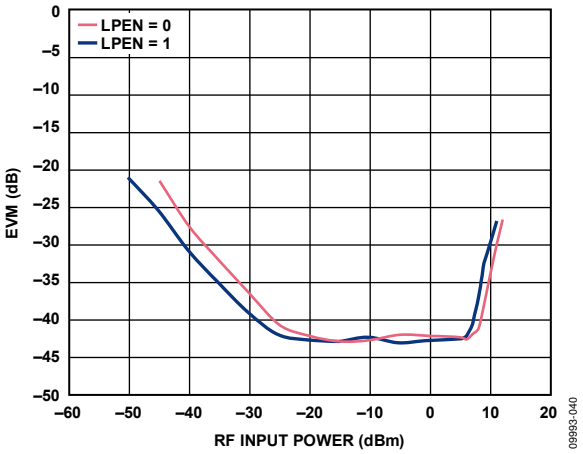

Figure 42. EVM Measurements at 900 MHz 4 QAM, Symbol Rate = 5 MHz, Baseband Frequency = 0 Hz IF
