

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Blackfin Embedded Processor with Codec

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

PROCESSOR FEATURES

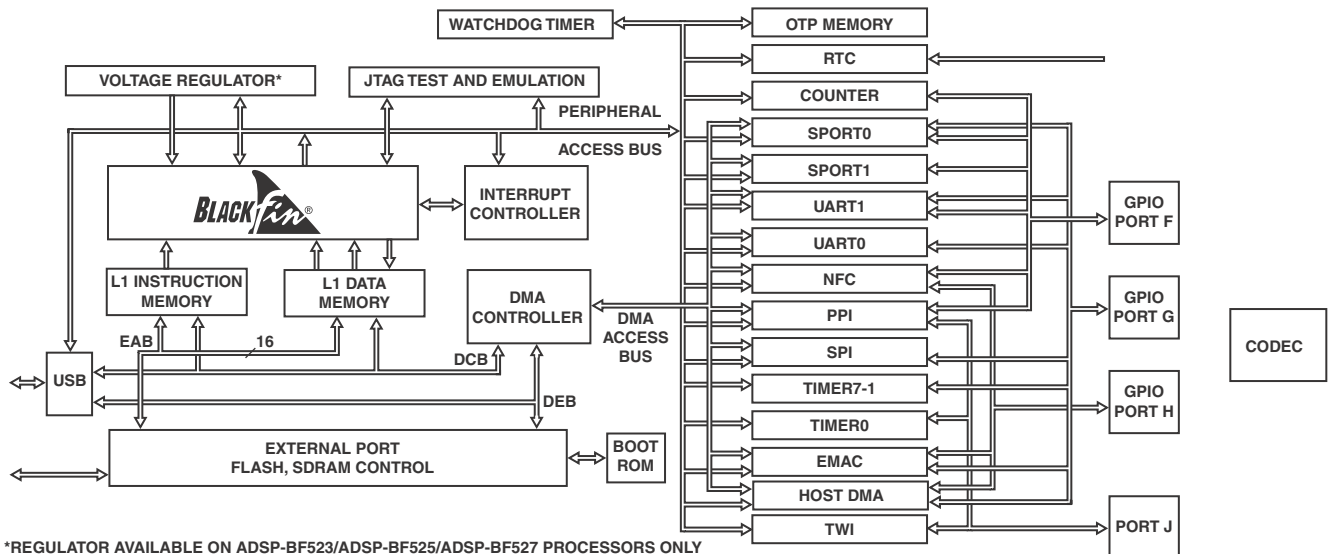

- Up to 600 MHz high performance Blackfin processor
 - RISC-like register and instruction model for ease of programming and compiler-friendly support
 - Advanced debug, trace, and performance monitoring
- Accepts a wide range of supply voltages for internal and I/O operations. See operating conditions in the published ADSP-BF52x processor data sheet.
- Programmable on-chip voltage regulator (ADSP-BF523/ADSP-BF525/ADSP-BF527 processors only)
- Embedded low power audio codec
- 289-ball (12 mm x 12 mm) CSP_BGA package
- 132K bytes of on-chip memory
- External memory controller with glueless support for SDRAM and asynchronous 8-bit and 16-bit memories
- Flexible booting options from external flash, SPI and TWI memory or from host devices including SPI, TWI, and UART
- Code security with Lockbox Secure Technology one-time-programmable (OTP) memory
- Memory management unit providing memory protection
- 2 dual-channel memory DMA controllers

EMBEDDED CODEC FEATURES

- Stereo, 24-bit ADCs and DACs
 - DAC SNR: 100 dB (A-weighted), THD: -80 dB at 48 kHz, 3.3 V
 - ADC SNR: 90 dB (A-weighted), THD: -80 dB at 48 kHz, 3.3 V
- Highly efficient headphone amplifier
- Stereo line input and monaural microphone input
- Low power
 - 7 mW stereo playback (1.8 V supply)
 - 14 mW record and playback (1.8 V supply)
- Low supply voltages
 - Analog: 1.8 V to 3.6 V
 - Digital core: 1.8 V min
 - Digital I/O: 1.8 V to 3.6 V
- 256 × f_s / 384 × f_s oversampling rate in normal mode; 250 × f_s / 272 × f_s oversampling rate in USB mode
- Audio sampling rates: 8 kHz, 11.025 kHz, 12 kHz, 16 kHz, 22.05 kHz, 24 kHz, 32 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, and 96 kHz

GENERAL DESCRIPTION

This document describes the differences between the ADSP-BF52xC and the ADSP-BF52x standard Blackfin® product. Please refer to the published ADSP-BF52x data sheet for general description and specifications. This document only describes the differences from that data sheet.

The ADSP-BF52xC processors add a low power, high quality stereo audio codec for portable digital audio applications with one set of stereo programmable gain amplifier (PGA) line inputs and one monaural microphone input. It features two 24-bit analog-to-digital converter (ADC) channels and two 24-bit digital-to-analog (DAC) converter channels.

The codec can operate as a master or a slave. It supports various master clock frequencies, including 12 MHz or 24 MHz for USB devices; standard $256 \times f_s$ or $384 \times f_s$ based rates, such as 12.288 MHz and 24.576 MHz; and many common audio sampling rates, such as 96 kHz, 88.2 kHz, 48 kHz, 44.1 kHz, 32 kHz, 24 kHz, 22.05 kHz, 16 kHz, 12 kHz, 11.025 kHz, and 8 kHz.

The codec can operate at power supplies as low as 1.8 V for the analog circuitry and as low as 1.8 V for the digital circuitry. The maximum voltage supply is 3.6 V for all supplies.

The codec software-programmable stereo output options provide the programmer with many application possibilities because the device can be used as a headphone driver or as a speaker driver. Its volume control functions provide a large range of gain control of the audio signal.

CODEC DESCRIPTION

The ADSP-BF52xC codec contains a central clock source, called the codec master clock (CODEC_MCLK) that produces a reference clock for all internal audio data processing and synchronization. When using an external clock source to drive the CODEC_MCLK pin, care should be taken to select a clock source with less than 50 ps of jitter. Without careful generation of the CODEC_MCLK signal, the digital audio quality will suffer.

To enable the codec to generate the central reference clock in a system, connect a crystal oscillator between the XTI/ CODEC_MCLK input pin and the XTO output pin.

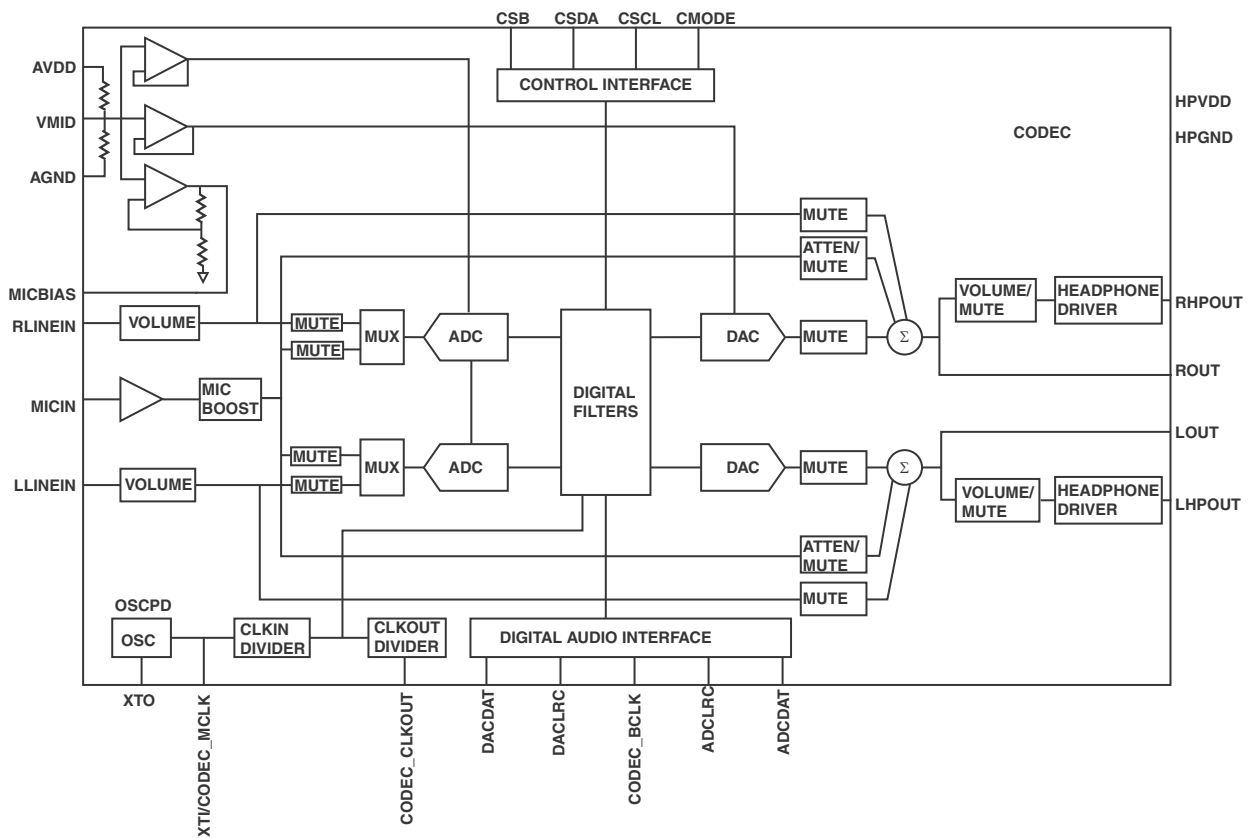

Figure 1. Codec Block Diagram

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

To allow an external device to generate the central reference clock, apply the external clock signal directly through the XTI/ CODEC_MCLK input pin. In this configuration, the oscillator circuit of the codec can be powered down by using the OSCPD bit (Register R6, Bit D5) to reduce power consumption.

To accommodate applications with very high frequency master clocks, the internal core reference clock of the codec can be set to either CODEC_MCLK or CODEC_MCLK divided by 2. This is enabled by adjusting the setting of the CLKDIV2 bit (Register R8, Bit D6). The CODEC_CLKOUT pin can also drive external clock sources with either the codec clock signal or codec clock divided by 2 by enabling the CLKODIV2 bit (Register R8, Bit D7).

ADC AND DAC

The codec contains a pair of oversampling Σ - Δ ADCs. The maximum ADC full-scale input level is $1.0 V_{rms}$ when $AVDD = 3.3 V$. If the input signal to the ADC exceeds this level, data overloading occurs and causes audible distortion.

The ADC can accept analog audio input from either the stereo line inputs or the monaural microphone input. Note that the ADC can only accept input from a single source, so the programmer must choose either the line inputs or the microphone input using the INSEL bit (Register R4, Bit D2). The digital data from the ADC output, once converted, is processed using the ADC filters.

Complementary to the Σ - Δ ADC channels, the codec contains a pair of oversampling DACs that convert the digital audio data from the internal DAC filters into an analog audio signal. The DAC output can also be muted by setting the DACMU bit (Register R5, Bit D3) in the control register.

ADC HIGH-PASS AND DAC DE-EMPHASIS FILTERS

The ADC and DAC employ separate digital filters that perform 24-bit signal processing. The digital filters are used for both record and playback modes and are optimized for each individual sampling rate used.

For recording mode operations, the unprocessed data from the ADC enters the ADC filters and is converted to the appropriate sampling frequency, then is output to the digital audio interface.

For playback mode operations, the DAC filters convert the digital audio interface data to oversampled data using a sampling rate selected by the programmer. The oversampled data is processed by the DAC and sent to the analog output mixer by enabling the DACSEL (Register R4, Bit D4).

Programmers have the option of setting up the device so that any dc offset in the input source signal is automatically detected and removed. To accomplish this, enable the digital high-pass filter (see Table 22 on Page 30 for characteristics) contained in the ADC digital filters by using the ADCHPD bit (Register R5, Bit D0).

In addition, programmers can implement digital de-emphasis by using the DEEMPH bits (Register R5, Bit D1 and Bit D2).

ANALOG AUDIO INTERFACES

The codec includes stereo single-ended line inputs and a monaural microphone input to the on-board ADC. Either the line inputs or the microphone input, but not both simultaneously, can be connected to the ADC by setting the INSEL bit (Register R4, Bit D2).

The codec also includes line and headphone outputs from the on-board DAC. The line or microphone inputs can be routed and mixed directly to the output terminals.

Stereo Line and Monaural Microphone Inputs

The single-ended stereo line inputs (RLINEIN and LLINEIN) are internally biased to VMID by way of a voltage divider between AVDD and AGND (see Figure 2). The line input signal can be connected to the internal ADC and, if desired, routed directly to the outputs via the bypass path by using the BYPASS bit (Register R4, Bit D3).

Figure 2. Line Input to ADC

The line input volume can be adjusted from -34.5 dB to $+33 \text{ dB}$ in steps of $+1.5 \text{ dB}$ by setting the LINVOL (Register R0, Bit D0 to Bit D5) and RINVOL (Register R1, Bit D0 to Bit D5) bits. By default the volume is independently adjustable for both right and left line inputs. However, if the LRINBOTH or RLINBOTH bit is programmed, both LINVOL and RINVOL are loaded with the same value. The programmer can also set the LINMUTE (Register R0, Bit D7) and RINMUTE (Register R1, Bit D7) bits to mute the line input signal to the ADC.

The high impedance monaural microphone input pin (MICIN, shown in Figure 3) has two gain stages and a microphone bias level (MICBIAS) that is internally biased to the VMID voltage level by way of a voltage divider between AVDD and AGND. The microphone input signal can be connected to the internal ADC and, if desired, routed directly to the outputs via the sidetone path by using the SIDETONE bit (Register R4, Bit D5).

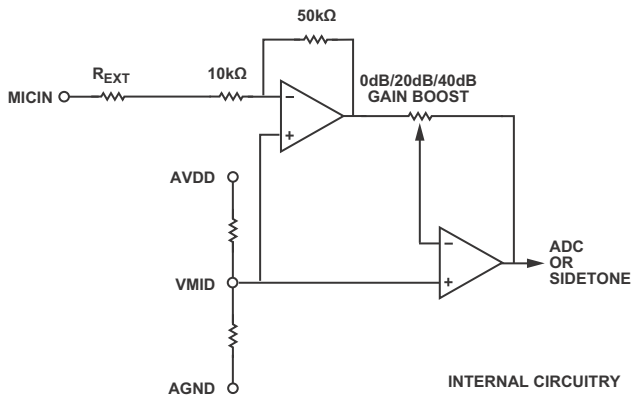

Figure 3. Microphone Input to ADC

The first gain stage is composed of a low noise operational amplifier set to an inverting configuration with integrated 50 kΩ feedback and 10 kΩ input resistors. The default microphone input signal gain is 14 dB. An external resistor (R_{EXT}) can be connected in series with the MICIN pin to reduce the first-stage gain of the microphone input signal to as low as 0 dB by using the following equation:

$$\text{Microphone Input Gain} = 50 \text{ k}\Omega / (10 \text{ k}\Omega + R_{EXT})$$

The second-stage gain of the microphone signal path is derived from the internal microphone boost circuitry. The available settings are 0 dB, 20 dB, and 40 dB and are controlled by the MICBOOST (Register R4, Bit D0) and MICBOOST2 (Register R4, Bit D8) bits. To achieve 20 dB of secondary gain boost, the programmer can select either MICBOOST or MICBOOST2. To achieve 40 dB of secondary microphone signal gain, the programmer must select both MICBOOST and MICBOOST2.

The MUTEMIC bit (Register R4, Bit D1) mutes the microphone input signal to the ADC.

When using either the line or microphone inputs, the maximum full-scale input to the ADC is 1.0 V rms when AVDD = 3.3 V. Do not apply an input voltage larger than full-scale to avoid overloading the ADC, which causes distortion of sound and deterioration of audio quality. For best sound quality in both microphone and line inputs, gain should be carefully configured so that the ADC receives a signal equal to its full-scale. This maximizes the signal-to-noise ratio for best total audio quality.

Bypass and Sidetone Paths to Output

The line and microphone inputs can be routed and mixed directly to the output terminals by programming the SIDETONE (Register R4, Bit D5) and BYPASS (Register R4, Bit D3) registers. In both modes, the analog input signal is routed directly to the output terminals and is not digitally converted. The bypass signal at the output mixer is the same level as the output of the PGA associated with each line input.

The sidetone signal at the output mixer can be attenuated from -6 dB to -15 dB in steps of -3 dB by configuring the SIDEATT (Register R4, Bit D6 and Bit D7) control register bits. The

selected level of attenuation occurs after the initial microphone signal amplification from the microphone first and second stage gains.

Line and Headphone Outputs

The DAC outputs, the microphone (the sidetone path), and the line inputs (the bypass path) are summed at an output mixer (see Figure 4). This output signal is then applied to both the stereo line outputs and stereo headphone outputs.

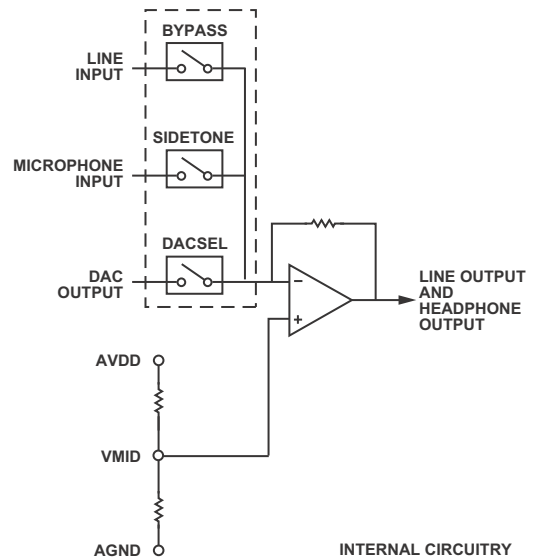

Figure 4. Output Signal Chain

The codec has a set of efficient headphone amplifier outputs, LHPOUT and RHPOUT, that are able to drive 16 Ω or 32 Ω headphones (shown in Figure 5).

Figure 5. Headphone Output

Like the line inputs, the LHPOUT and RHPOUT volumes, by default, are independently adjusted by setting the LHPVOL (Register R2, Bit D0 to Bit D6) and RHPVOL (Register R3, Bit D0 to Bit D6) bits of the headphone output control registers. The headphone outputs can be muted by writing codes less than 0110000 to the LHPVOL and RHPVOL bits.

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

The programmer can simultaneously load the volume control of both channels by writing to the LRHPBOTH (Register R2, Bit D8) and RLHPBOTH (Register R3, Bit D8) bits of the left- or right-channel DAC volume registers.

The maximum output level of the headphone outputs is 1.0 V rms when AVDD and HPVDD = 3.3 V. To suppress audible pops and clicks, the headphone and line outputs are held at the VMID dc voltage level when the device is set to standby mode or when the headphone outputs are muted.

The stereo line outputs of the codec, the LOUT and ROUT pins, can drive a load impedance of 10 kΩ and 50 pF. The line output signal levels are not adjustable at the output mixer, which has a fixed gain of 0 dB. The maximum output level of the line outputs is 1.0 V rms when AVDD = 3.3 V.

DIGITAL AUDIO INTERFACE

The digital audio input can support the following digital audio communication protocols: right-justified mode, left-justified mode, I²S mode, and frame sync mode. See [Figure 6 on Page 6](#) through [Figure 10 on Page 7](#).

The mode selection is performed by writing to the FORMAT bits of the digital audio interface register (Register R7, Bit D1 and Bit D0). All modes are MSB first and operate with data of 16 to 32 bits.

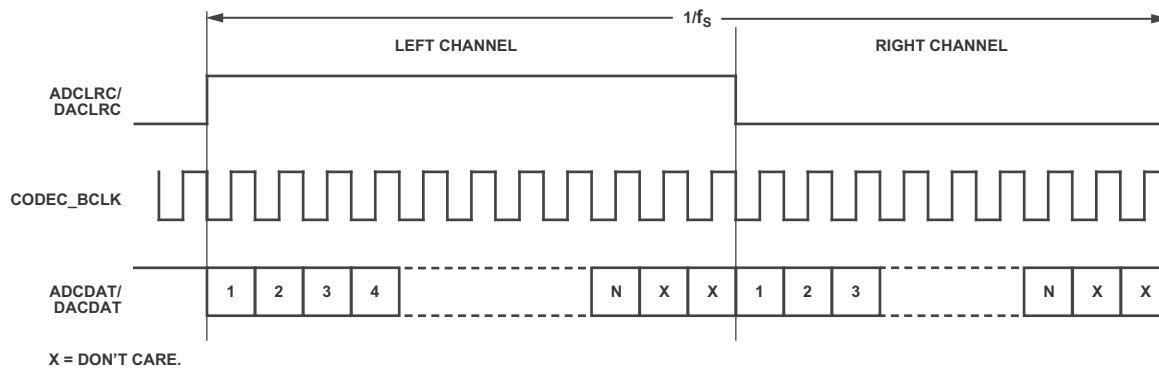

Figure 6. Left-Justified Audio Input Mode

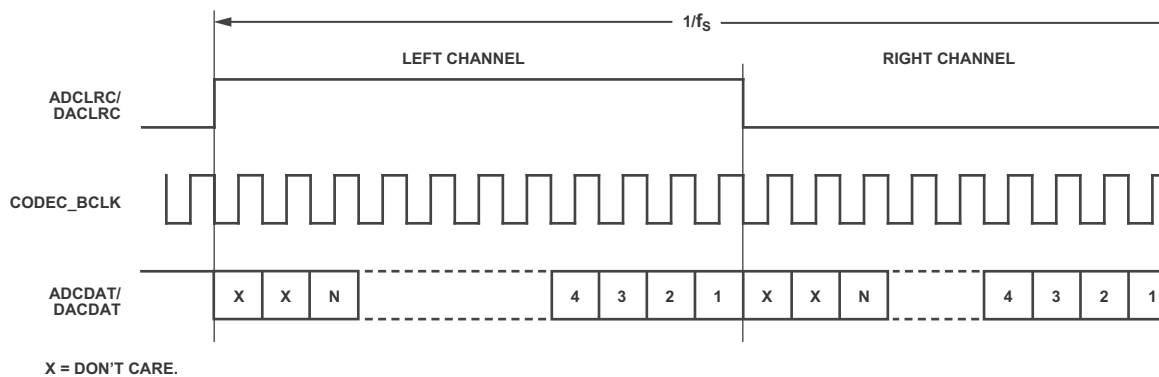

Figure 7. Right-Justified Audio Input Mode

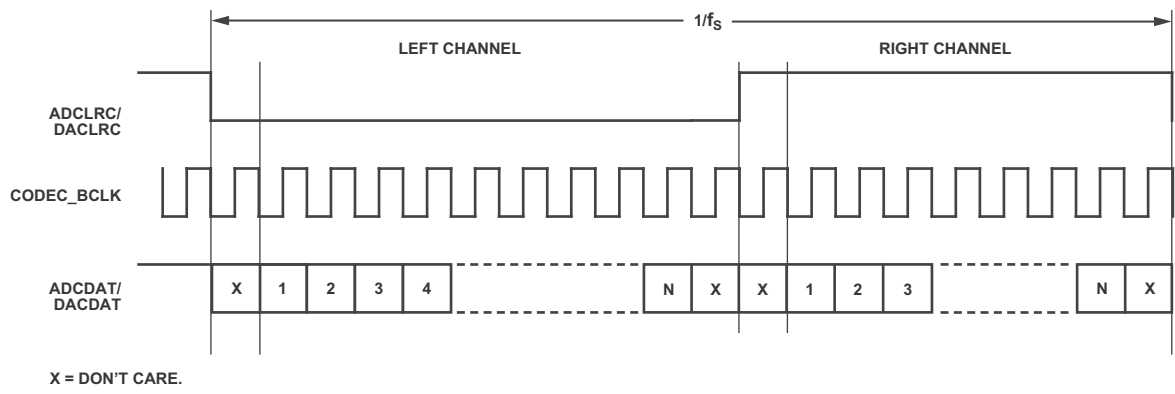

Figure 8. I²S Audio Input Mode

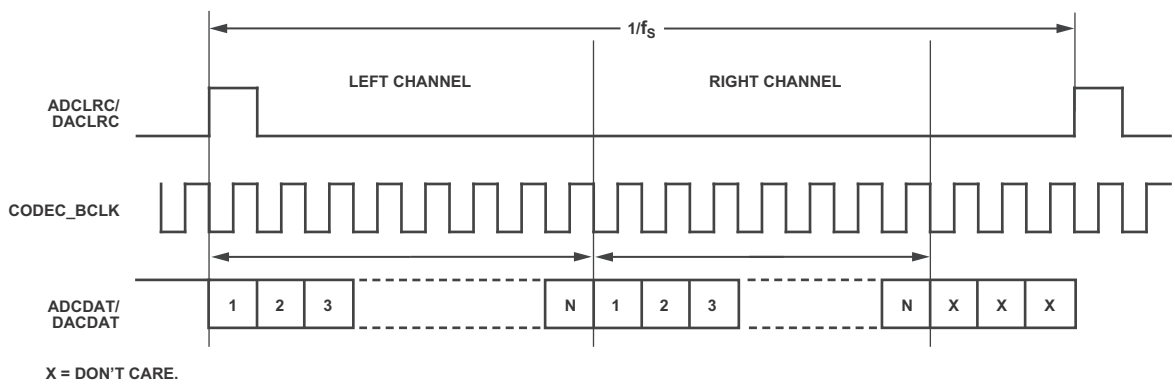

Figure 9. Frame Sync/PCM Mode Audio Input (Submode 1) [Bit LRP = 0]

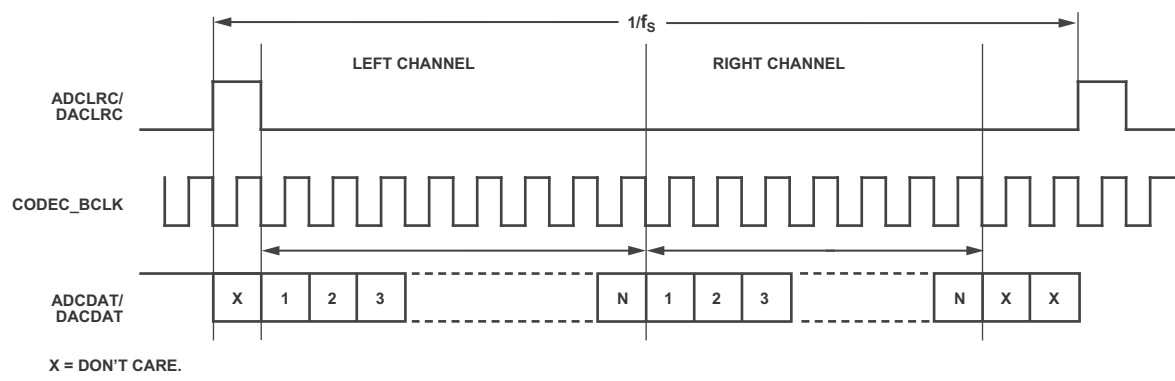

Figure 10. Frame Sync/PCM Mode Audio Input (Submode 2) [Bit LRP = 1]

Recording Mode

The digital audio interface sends the ADC digital filter data to the ADCDAT output pin for recording. The ADCDAT data stream multiplexes the left- and right-channel audio data in the time domain. The ADCLRC clock signal separates left- and right-channel digital audio frames on the ADCDAT lines.

The CODEC_BCLK signal clocks the digital audio data within the frames. The CODEC_BCLK signal is either an input or an output depending on whether the codec is in master or slave mode. During a recording operation, ADCDAT and ADCLRC must be synchronous to the CODEC_BCLK signal to avoid data corruption.

Playback Mode

The digital audio interface receives data on the DACDAT input pin for playback. The digital audio data stream on the DACDAT pin is time-domain-multiplexed left and right channel audio data. The DACLRC clock signal separates left and right channel digital audio frames on the DACDAT lines.

The CODEC_BCLK signal clocks the digital audio data within the frames. The CODEC_BCLK signal is either an input or an output depending on whether the codec is in master or slave mode. During a playback operation, DACDAT and DACLRC must be synchronous to the CODEC_BCLK signal to avoid data corruption.

Digital Audio Data Sampling Rate

To accommodate a wide variety of commonly used DAC and ADC sampling rates, the codec allows for two modes of operation, normal and USB, selected by the USB bit (Register R8, Bit D0).

The sampling rate is generated as a fixed divider from the CODEC_MCLK signal. Because all audio processing references the CODEC_MCLK signal, corruption of this signal will corrupt the quality of the audio at the codec output. The ADCLRC/ ADCDAT/CODEC_BCLK or DACLRC/DACDAT/ CODEC_BCLK signals must be synchronized with CODEC_MCLK in the digital audio interface circuit.

CODEC_MCLK must be faster or equal to the CODEC_BCLK frequency to guarantee that no data is lost during data synchronization. The CODEC_BCLK frequency should be greater than the sampling rate \times word length \times 2. Ensuring that the CODEC_BCLK frequency is greater than this, guarantees that all valid data bits are captured by the digital audio interface circuitry. For example, if a 32 kHz digital audio sampling rate with a 32-bit word length is desired, CODEC_BCLK = 2.048 MHz.

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

Normal Mode

In normal mode, the codec supports digital audio sampling rates from 8 kHz to 96 kHz. Normal mode supports $256 \times f_s$ and $384 \times f_s$ based clocks. To select the desired sampling rate, the programmer must set the appropriate sampling rate register in

the SR control bits (Register R8, Bit D2 to Bit D5) and match this selection to the core clock frequency that is pulsed on the CODEC_MCLK pin. See [Table 1](#) for sampling rates in normal mode.

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

USB Mode

In USB mode, the codec supports digital audio sampling rates from 8 kHz to 96 kHz. USB mode is enabled on the codec to support the common universal serial bus (USB) clock rate of

12 MHz, or to support 24 MHz if the CLKDIV2 control register bit is activated. The programmer must set the appropriate sampling rate in the SR control bits (Register R8, Bit D2 to Bit D5). See [Table 2](#) for sampling rates in USB mode.

¹ CODEC_BCLK frequency is for master mode and slave right-justified mode only.

ADSP-BF522C/ADSP-BF523C/ADSP-BF524C/ADSP-BF525C/ADSP-BF526C/ADSP-BF527C

SOFTWARE CONTROL INTERFACE

The software control interface provides access to the programmer-selectable control registers and can operate with a 2-wire (TWI) or 3-wire (SPI) interface, depending on the setting of the CMODE pin. If the CMODE pin is set to 0, the 2-wire interface is selected; if 1, the 3-wire interface is selected.

Within each control register is a control data-word consisting of 16 bits, MSB first. Bit B15 to Bit B9 are the register map address, and Bit B8 to Bit B0 are register data for the associated register map.

When 2-wire (TWI) mode is selected, CSDA generates the serial control data-word; CSCL clocks the serial data; and CSB determines the TWI device address. If the CSB pin is set to 0, the address selected is 0011010; if 1, the address is 0011011.

When 3-wire (SPI) mode is selected, CSDA generates the control data-word, CSCL clocks the control data-word into the codec, and CSB latches in the control data-word.

Figure 11. Codec SPI Serial Interface

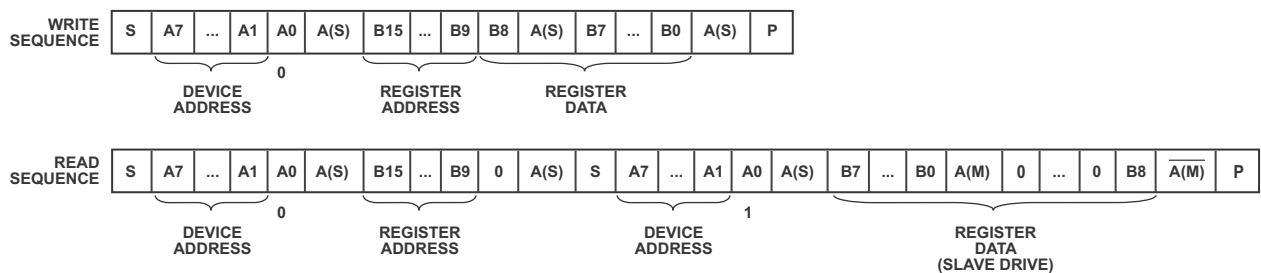

Figure 12. Codec TWI Serial Interface

S/P = START/STOP BIT.
 A0 = I²C R/W BIT.
 A(S) = ACKNOWLEDGE BY SLAVE.
 A(M) = ACKNOWLEDGE BY MASTER.
 A(M) = ACKNOWLEDGE BY MASTER (INVERSION).

ABSOLUTE MAXIMUM RATINGS

See absolute maximum ratings in the published ADSP-BF52x processor data sheet.

ESD SENSITIVITY

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PACKAGE INFORMATION

The information presented in [Figure 17](#) and [Table 15](#) provides details about the package branding for the ADSP-BF52xC processor. For a complete listing of product availability, see [Ordering Guide on Page 36](#).

Parameter	Test Conditions ¹	Min	Max	Unit
t_{SCS}	Start condition setup time	600		ns
t_{SCH}	Start condition hold time	600		ns
t_{PH}	CSCL pulse width high	600		ns
t_{PL}	CSCL pulse width low	1.3		μ s
f_{SCL}	CSCL frequency	0	526	kHz
t_{DS}	Data setup time	100		ns
t_{DH}	Data hold time		900	ns
t_{RT}	CSDA and CSCL rise time		300	ns
t_{FT}	CSDA and CSCL fall time		300	ns
t_{HCS}	Stop condition setup time	600		ns

¹ AVDD, HPVDD, $V_{DDEXT} = 3.3$ V, AGND = 0 V, $T_A = +25^\circ\text{C}$, Slave Mode, $f_s = 48$ kHz, XTI/CODEC_MCLK = $256 \times f_s$ unless otherwise stated.
