

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## Micro-Stepping Motor Driver

### Introduction

The AMIS-30542 is a micro-stepping stepper motor driver for bipolar stepper motors. The chip is connected through I/O pins and a SPI interface with an external microcontroller. It has an on-chip voltage regulator, reset-output and watchdog reset, able to supply peripheral devices. AMIS-30542 contains a current-translation table and takes the next micro-step depending on the clock signal on the "NXT" input pin and the status of the "DIR" (=direction) register or input pin. The chip provides a so-called "speed and load angle" output. This allows the creation of stall detection algorithms and control loops based on load-angle to adjust torque and speed. It is using a proprietary PWM algorithm for reliable current control.

The AMIS-30542 is implemented in I2T100 technology, enabling both high-voltage analog circuitry and digital functionality on the same chip. The chip is fully compatible with the automotive voltage requirements.

The AMIS-30542 is ideally suited for general-purpose stepper motor applications in the automotive, industrial, medical, and marine environment. With the on-chip voltage regulator it further reduces the BOM for mechatronic stepper applications.

### Key Features

- Dual H-Bridge for 2-Phase Stepper Motors
- Programmable Peak-Current Up to 2.2 A Continuous† (5 A Short Time) Using a 5-bit Current DAC
- On-Chip Current Translator
- SPI Interface
- Speed and Load Angle Output
- Seven Step Modes from Full Step Up to 32 Micro-Steps
- Fully Integrated Current-Sense
- PWM Current Control with Automatic Selection of Fast and Slow Decay
- Low EMC PWM with Selectable Voltage Slopes
- Active Fly-Back Diodes
- Full Output Protection and Diagnosis
- Thermal Warning and Shutdown
- Compatible with 5 V and 3.3 V Microcontrollers
- Integrated 5 V Regulator to Supply External Microcontroller
- Integrated Reset Function to Reset External Microcontroller
- Integrated Watchdog Function
- These Devices are Pb-Free and are RoHS Compliant\*

†Output current level may be limited by ambient temperature and heat sinking.  
\*For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

EQUIVALENT SCHEMATICS

Following figure gives the equivalent schematics of the user relevant inputs and outputs. The diagrams are simplified representations of the circuits used.

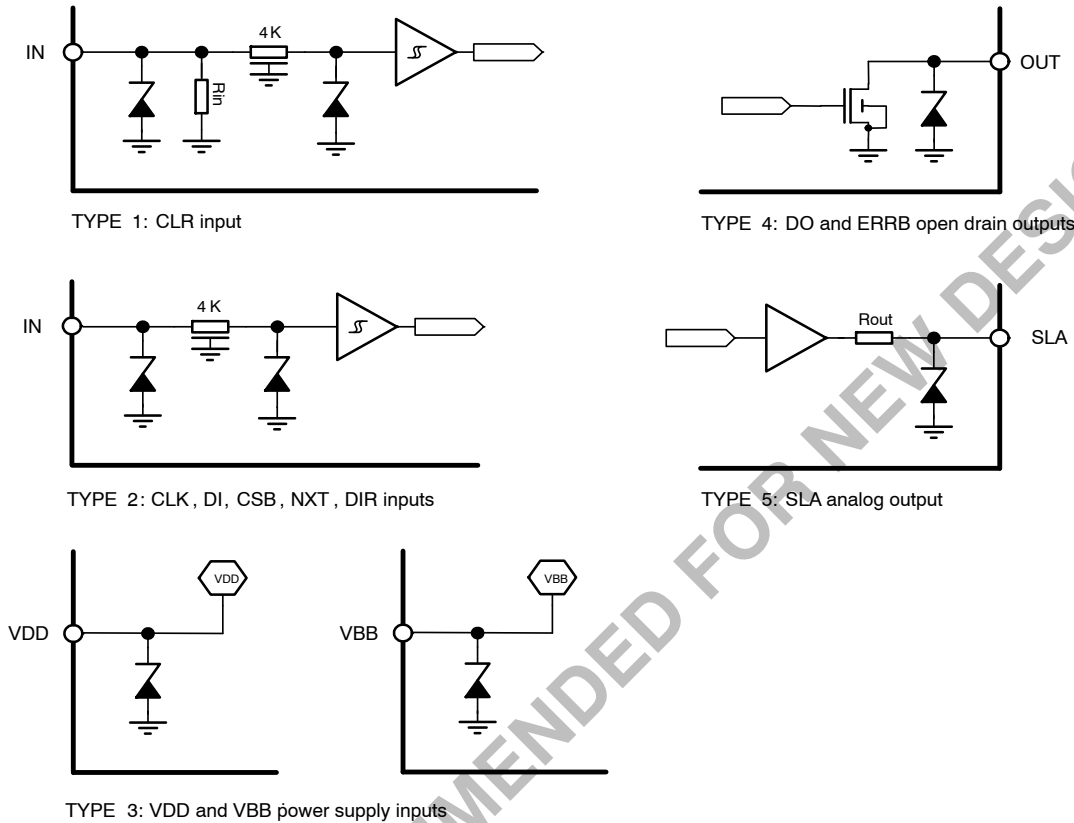

Figure 3. In- and Output Equivalent Diagrams

PACKAGE THERMAL CHARACTERISTICS

The AMIS-30542 is available in a NQFP32 package. For cooling optimizations, the NQFP has an exposed thermal pad which has to be soldered to the PCB ground plane. The ground plane needs thermal vias to conduct the heat to the bottom layer. Figure 3 gives an example for good power distribution solutions.

For precise thermal cooling calculations the major thermal resistances of the device are given. The thermal media to which the power of the devices has to be given are:

- Static environmental air (via the case)
- PCB board copper area (via the exposed pad)

The thermal resistances are presented in Table 5: DC Parameters.

The major thermal resistances of the device are the  $R_{th}$  from the junction to the ambient ( $R_{thja}$ ) and the overall  $R_{th}$  from the junction to exposed pad ( $R_{thjp}$ ). In Table 5 below one can find the values for the  $R_{thja}$  and  $R_{thjp}$ , simulated according to JESD-51:

The  $R_{thja}$  for 2S2P is simulated conform JEDEC JESD-51 as follows:

- A 4-layer printed circuit board with inner power planes and outer (top and bottom) signal layers is used
- Board thickness is 1.46 mm (FR4 PCB material)
- The 2 signal layers: 70  $\mu\text{m}$  thick copper with an area of 5500  $\text{mm}^2$  copper and 20% conductivity
- The 2 power internal planes: 36  $\mu\text{m}$  thick copper with an area of 5500  $\text{mm}^2$  copper and 90% conductivity

The  $R_{thja}$  for 1S0P is simulated conform to JEDEC JESD-51 as follows:

- A 1-layer printed circuit board with only 1 layer
- Board thickness is 1.46 mm (FR4 PCB material)
- The layer has a thickness of 70  $\mu\text{m}$  copper with an area of 5500  $\text{mm}^2$  copper and 20% conductivity

**ELECTRICAL SPECIFICATION**

**Recommend Operation Conditions**

Operating ranges define the limits for functional operation and parametric characteristics of the device. Note that the functionality of the chip outside these operating

ranges is not guaranteed. Operating outside the recommended operating ranges for extended periods of time may affect device reliability.

**Table 4. OPERATING RANGES**

Symbol	Parameter	Min	Max	Unit
$V_{BB}$	Analog DC Supply	+6	+30	V
$T_J$	Junction Temperature (Note 5)	-40	+172	°C

5. No more than 100 cumulative hours in life time above  $T_{tw}$ .

DEVICE NOT RECOMMENDED FOR NEW DESIGN

FUNCTIONAL DESCRIPTION

**H-Bridge Drivers**

A full H-bridge is integrated for each of the two stator windings. Each H-bridge consists of two low-side and two high-side N-type MOSFET switches. Writing logic ‘0’ in bit <MOTEN> disables all drivers (high-impedance). Writing logic ‘1’ in this bit enables both bridges and current can flow in the motor stator windings.

In order to avoid large currents through the H-bridge switches, it is guaranteed that the top- and bottom-switches of the same half-bridge are never conductive simultaneously (interlock delay).

A two-stage protection against shorts on motor lines is implemented. In a first stage, the current in the driver is limited. Secondly, when excessive voltage is sensed across the transistor, the transistor is switched off.

In order to reduce the radiated/conducted emission, voltage slope control is implemented in the output switches. The output slope is defined by the gate-drain capacitance of output transistor and the (limited) current that drives the gate. There are two trimming bits for slope control (see Table 14 SPI Control Parameter Overview EMC[1:0]).

The power transistors are equipped with so-called “active diodes”: when a current is forced through the transistor switch in the reverse direction, i.e. from source to drain, then the transistor is switched on. This ensures that most of the current flows through the channel of the transistor instead of through the inherent parasitic drain-bulk diode of the transistor.

Depending on the desired current range and the micro-step position at hand, the  $R_{DS(on)}$  of the low-side

transistors will be adapted such that excellent current-sense accuracy is maintained. The  $R_{DS(on)}$  of the high-side transistors remain unchanged; see Table 5 DC Parameters for more details.

**PWM Current Control**

A PWM comparator compares continuously the actual winding current with the requested current and feeds back the information to a digital regulation loop. This loop then generates a PWM signal, which turns on/off the H-bridge switches. The switching points of the PWM duty-cycle are synchronized to the on-chip PWM clock. The frequency of the PWM controller can be doubled and an artificial jitter can be added (see Table 14 SPI Control Parameter Overview PWMJ). The PWM frequency will not vary with changes in the supply voltage. Also variations in motor-speed or load-conditions of the motor have no effect. There are no external components required to adjust the PWM frequency.

**Automatic Forward and Slow-Fast Decay**

The PWM generation is in steady-state using a combination of forward and slow-decay. The absence of fast-decay in this mode, guarantees the lowest possible current-ripple “by design”. For transients to lower current levels, fast-decay is automatically activated to allow high-speed response. The selection of fast or slow decay is completely transparent for the user and no additional parameters are required for operation.

Figure 8. Forward and Slow/Fast Decay PWM

**Automatic Duty Cycle Adaptation**

In case the supply voltage is lower than  $2 \cdot B_{emf}$ , then the duty cycle of the PWM is adapted automatically to  $> 50\%$  to maintain the requested average current in the coils. This

process is completely automatic and requires no additional parameters for operation. The over-all current-ripple is divided by two if PWM frequency is doubled (see Table 14 SPI Control Parameter Overview PWMF)

Figure 9. Automatic Duty Cycle Adaptation

**Step Translator and Step Mode**

The step translator provides the control of the motor by means of SPI register Stepmode: SM[2:0], SPI register DIRCNTRL and input pins DIR and NXT. It is translating consecutive steps in corresponding currents in both motor coils for a given step mode.

One out of seven possible stepping modes can be selected through SPI-bits SM[2:0] (see Table 14 SPI Control Parameter Overview ) After power-on or hard reset, the coil-current translator is set to the default 1/32 micro-stepping at position '0'. Upon changing the step mode, the translator jumps to position 0\* of the

corresponding stepping mode. When remaining in the same step mode, subsequent translator positions are all in the same column and increased or decreased with 1. Table 10 lists the output current vs. the translator position.

As shown in Figure 10 the output current-pairs can be projected approximately on a circle in the  $(I_x, I_y)$  plane. There are, however, two exceptions: uncompensated half step and full step. In these step modes the currents are not regulated to a fraction of  $I_{max}$  but are in all intermediate steps regulated at 100%. In the  $(I_x, I_y)$  plane the current-pairs are projected on a square. Table 9 lists the output current vs. the translator position for these cases.

Table 9. SQUARE TRANSLATOR TABLE FOR FULL STEP AND UNCOMPENSATED HALF STEP

MSP[6:0]	Stepmode ( SM[2:0] )		% of $I_{max}$	
	101	110	Coil x	Coil y

Figure 10. Translator Table: Circular and Square

**Direction**

The direction of rotation is selected by means of following combination of the DIR input pin and the SPI-controlled direction bit <DIRCTRL>. (see Table 14 SPI Control Parameter Overview)

**NXT input**

Changes on the NXT input will move the motor current one step up/down in the translator table (even when the motor is disabled: <MOTEN> = 0). Depending on the

NXT-polarity bit <NXTP> (see Table 14 SPI Control Parameter Overview), the next step is initiated either on the rising edge or the falling edge of the NXT input.

**Translator Position**

The translator position MSP[6:0] can be read in SPI Status Register 3 (See Table 15 SR3). This is a 7-bit number equivalent to the 1/32<sup>th</sup> micro-step from see Table 10 “Circular Translator Table”. The translator position is updated immediately following a NXT trigger.

Figure 11. Translator Position Timing Diagram

**Synchronization of Step Mode and NXT Input**

When step mode is re-programmed to another resolution (Figure 12), then this is put in effect immediately upon the first arriving “NXT” input. If the micro-stepping resolution is increased, the coil currents will be regulated to the nearest micro-step, according to the fixed grid of the increased resolution. If however the micro-stepping resolution is decreased, then it is possible to introduce an offset (or phase shift) in the micro-step translator table.

If the step resolution is decreased at a translator table position that is shared both by the old and new resolution setting, then the offset is zero and micro-stepping is proceeds according to the translator table.

If the translator position is **not** shared both by the old and new resolution setting, then the micro-stepping proceeds with an offset relative to the translator table (See Figure 12 right hand side).

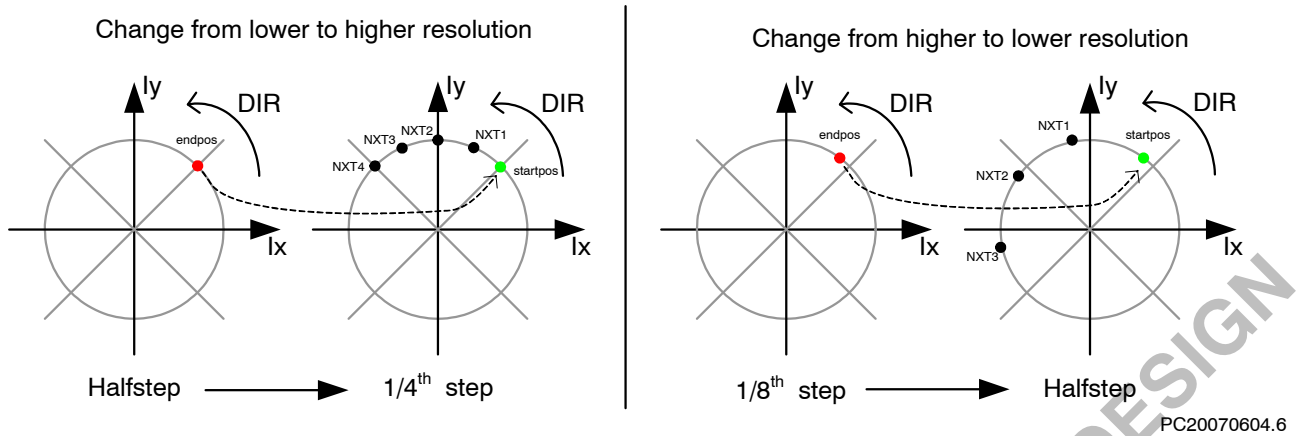

Figure 12. NXT-Step Mode Synchronization

**Left:** Change from lower to higher resolution. The left-hand side depicts the ending half-step position during which a new step mode resolution was programmed. The right-hand side diagram shows the effect of subsequent NXT commands on the micro-step position.

**Right:** Change from higher to lower resolution. The left-hand side depicts the ending micro-step position during which a new step mode resolution was programmed. The right-hand side diagram shows the effect of subsequent NXT commands on the half-step position.

**Note:** It is advised to reduce the micro-stepping resolution only at micro-step positions that overlap with desired micro-step positions of the new resolution.

**Programmable Peak-Current**

The amplitude of the current waveform in the motor coils (coil peak current =  $I_{max}$ ) is adjusted by means of an SPI parameter “CUR[4:0]” (see Table 14 SPI Control Parameter

Overview). Whenever this parameter is changed, the coil-currents will be updated immediately at the next PWM period. Figure 13 presents the Peak-Current and Current Ratings in conjunction to the Current setting CUR[4:0].

Figure 13. Programmable Peak-Current Overview

**Speed and Load Angle Output**

The SLA-pin provides an output voltage that indicates the level of the Back-e.m.f. voltage of the motor. This Back-e.m.f. voltage is sampled during every so-called "coil

current zero crossings". Per coil, two zero-current positions exist per electrical period, yielding in total four zero-current observation points per electrical period.

**Figure 14. Principle of BEMF Measurement**

Because of the relatively high recirculation currents in the coil during current decay, the coil voltage  $V_{COIL}$  shows a transient behavior. As this transient is not always desired in application software, two operating modes can be selected by means of the bit <SLAT> (see "SLA-transparency" in Table 14 SPI Control Parameter Overview). The SLA pin shows in "transparent mode" full visibility of the voltage transient behavior. This allows a sanity-check of the speed-setting versus motor operation and characteristics and supply voltage levels. If the bit "SLAT" is cleared, then only the voltage samples at the end of each coil current zero crossing are visible on the SLA-pin. Because the transient

behavior of the coil voltage is not visible anymore, this mode generates smoother Back e.m.f. input for post-processing, e.g. by software.

In order to bring the sampled Back e.m.f. to a descent output level (0 V to 5 V), the sampled coil voltage  $V_{COIL}$  is divided by 2 or by 4. This divider is set through an SPI bit <SLAG>. (see Table 14 SPI Control Parameter Overview)

The following drawing illustrates the operation of the SLA-pin and the transparency-bit. "PWMsh" and " $I_{COIL} = 0$ " are internal signals that define together with SLAT the sampling and hold moments of the coil voltage.

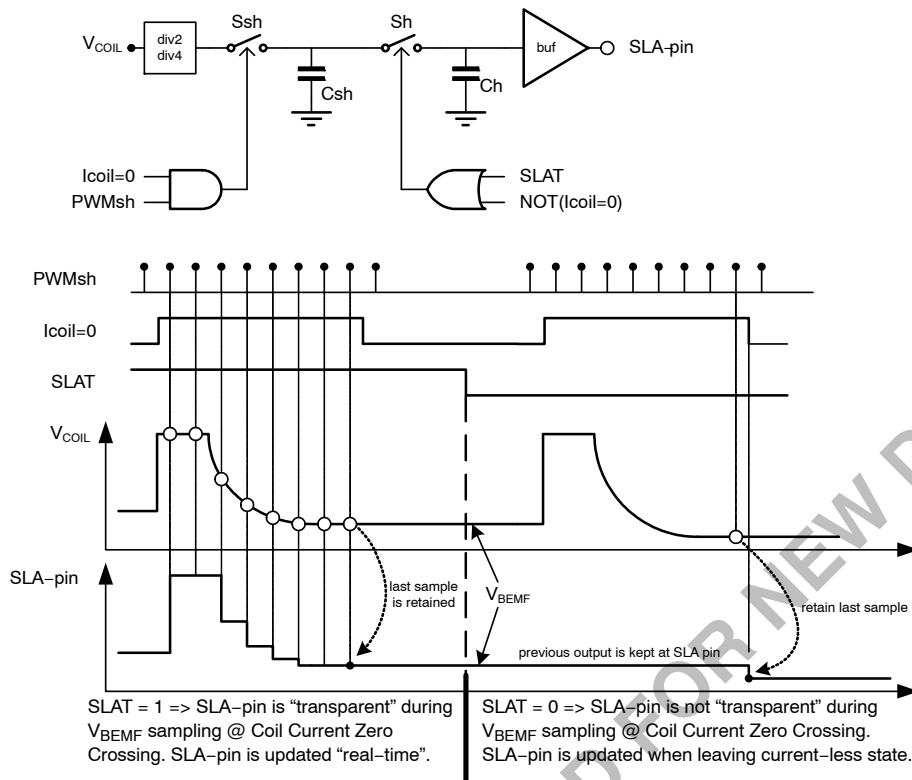

Figure 15. Timing Diagram of SLA-Pin

### Warning, Error Detection and Diagnostics Feedback

#### Thermal Warning and Shutdown

When junction temperature rises above  $T_{TW}$ , the thermal warning bit  $\langle TW \rangle$  is set (Table 16 SPI Status registers Address SR0). If junction temperature increases above thermal shutdown level, then the circuit goes in "Thermal Shutdown" mode ( $\langle TSD \rangle$ ) and all driver transistors are disabled (high impedance) (see Table 16 SPI Status registers Address SR2). The conditions to reset flag  $\langle TSD \rangle$  is to be at a temperature lower than  $T_{TW}$  and to clear the  $\langle TSD \rangle$  flag by reading it using any SPI read command.

#### Overcurrent Detection

The overcurrent detection circuit monitors the load current in each activated output stage. If the load current exceeds the over-current detection threshold, then the overcurrent flag is set and the drivers are switched off to reduce the power dissipation and to protect the integrated circuit. Each driver transistor has an individual detection bit in (see Table 16 SPI Status registers Address SR1 and SR2:  $\langle OVCxij \rangle$  and  $\langle OVCIij \rangle$ ). Error condition is latched and the microcontroller needs to clean the status bits to reactivate the drivers.

**Note:** Successive reading the SPI StatusRegisters 1 and 2 in case of a short circuit condition, may lead to damage to the drivers.

#### Open Coil/Current Not Reached Detection

Open coil detection is based on the observation of 100% duty cycle of the PWM regulator. If in a coil 100% duty cycle is detected for longer than 200 ms then the related driver transistors are disabled (high-impedance) and an appropriate bit in the SPI status register is set ( $\langle OPENX \rangle$  or  $\langle OPENY \rangle$ ). (Table 16)

When the resistance of a motor coil is very large and the supply voltage is low, it can happen that the motor driver is not able to deliver the requested current to the motor. Under these conditions the PWM controller duty cycle will be 100% and after 200 ms the error pin and  $\langle OPENX \rangle$ ,  $\langle OPENY \rangle$  will flag this situation (motor current is kept alive). This feature can be used to test if the operating conditions (supply voltage, motor coil resistance) still allow reaching the requested coil-current or else the coil current should be reduced.

#### Charge Pump Failure

The charge pump is an important circuit that guarantees low  $R_{DS(on)}$  for all drivers, especially for low supply voltages. If supply voltage is too low or external components are not properly connected to guarantee  $R_{DS(on)}$  of the drivers, then the bit  $\langle CPFAIL \rangle$  is set (Table 16). Also after POR the charge pump voltage will need some time to exceed the required threshold. During that time  $\langle CPFAIL \rangle$  will be set to "1".

**Error Output**

This is a digital output to flag a problem to the external microcontroller. The signal on this output is active low and the logic combination of:

$$\text{NOT}(\text{ERRB}) = \langle \text{TW} \rangle \text{ OR } \langle \text{TSD} \rangle \text{ OR } \langle \text{OVCXi}j \rangle \text{ OR } \langle \text{OVCI}ij \rangle \text{ OR } \langle \text{OPENi} \rangle \text{ OR } \langle \text{CPFAIL} \rangle$$

**Logic Supply Regulator**

AMIS-30542 has an on-chip 5 V low-drop regulator with external capacitor to supply the digital part of the chip, some low-voltage analog blocks and external circuitry. The voltage level is derived from an internal bandgap reference. To calculate the available drive-current for external

circuitry, the specified  $I_{\text{load}}$  should be reduced with the consumption of internal circuitry (unloaded outputs) and the loads connected to logic outputs. See Table 5. DC parameters

**Power-On Reset (POR) Function**

The open drain output pin  $\overline{\text{POR}}/\text{WD}$  provides an “active low” reset for external purposes. At powerup of AMIS-30542, this pin will be kept low for some time to reset for example an external microcontroller. A small analogue filter avoids resetting due to spikes or noise on the  $V_{\text{DD}}$  supply.

Figure 16. Power-on-Reset Timing Diagram

**Watchdog Function**

The watchdog function is enabled/disabled through  $\langle \text{WDEN} \rangle$  bit (Table 13: SPI CONTROL REGISTERS (ALL SPI control registers have Read/Write Access and default to “0” after power-on or hard reset.)). Once this bit has been set to “1” (watchdog enable), the microcontroller needs to re-write this bit to clear an internal timer before the watchdog timeout interval expires. In case the timer is activated and  $\text{WDEN}$  is acknowledged too early (before  $t_{\text{WDPR}}$ ) or not within the interval (after  $t_{\text{WDTO}}$ ), then a reset of the microcontroller will occur through  $\overline{\text{POR}}/\text{WD}$  pin. In addition, a warm/cold boot bit  $\langle \text{WD} \rangle$  is available (see Tables 16 and 17) for further processing when the external microcontroller is alive again.

**CLR pin (=Hard Reset)**

Logic 0 on CLR pin allows normal operation of the chip. To reset the complete digital inside AMIS-30542, the input CLR needs to be pulled to logic 1 during minimum time given by  $t_{\text{CLR}}$ . (Table 6 AC Parameters). This reset function clears all internal registers without the need of a power-cycle, except in sleep mode. The operation of all

analog circuits is depending on the reset state of the digital, charge pump remains active. Logic 0 on CLR pin resumes normal operation again.

The voltage regulator remains functional during and after the reset and the  $\overline{\text{POR}}/\text{WD}$  pin is not activated. Watchdog function is reset completely.

**Sleep Mode**

The bit  $\langle \text{SLP} \rangle$  in SPI Control Register 2 (See Table 12) is provided to enter a so-called “sleep mode”. This mode allows reduction of current-consumption when the motor is not in operation. The effect of sleep mode is as follows:

- The drivers are put in HiZ
- All analog circuits are disabled and in low-power mode
- All internal registers are maintaining their logic content
- NXT and DIR inputs are forbidden
- SPI communication remains possible (slight current increase during SPI communication)
- Oscillator and digital clocks are silent, except during SPI communication

The voltage regulator remains active but with reduced current-output capability ( $I_{LOADSLP}$ ). The watchdog timer stops running and its value is kept in the counter. Upon leaving sleep mode, this timer continues from the value it had before entering sleep mode.

Normal operation is resumed after writing logic '0' to bit <SLP>. A startup time is needed for the charge pump to stabilize. After this time, NXT commands can be issued.

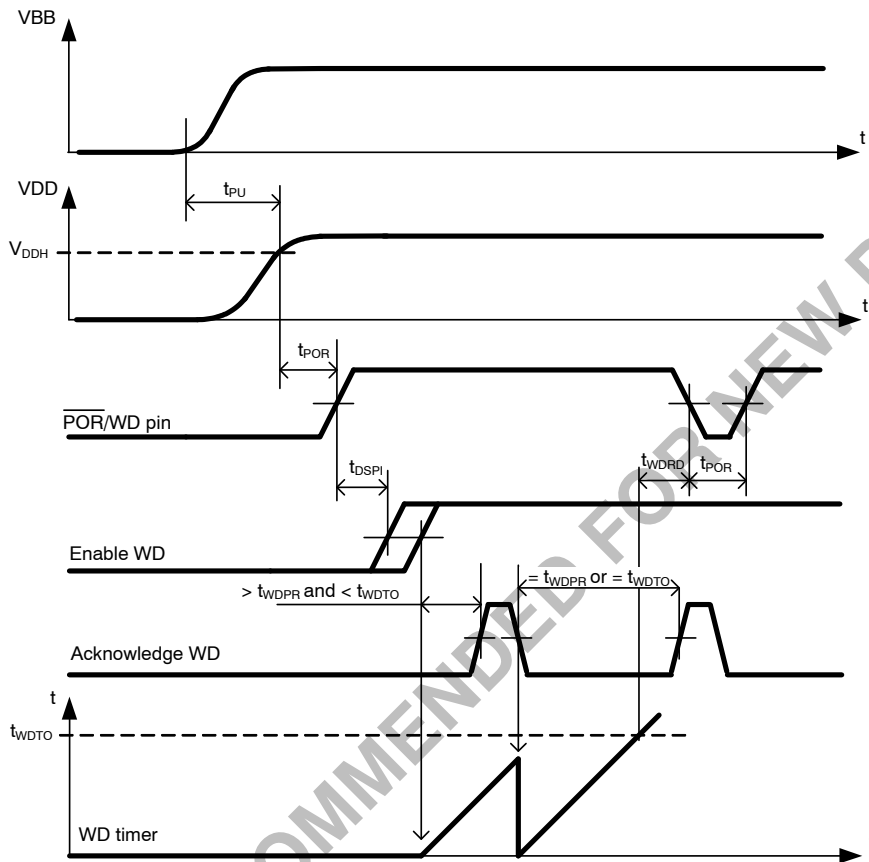

Figure 17. Watchdog Timing Diagram

NOTE:  $t_{DSPI}$  is the time needed by the external microcontroller to shift-in the <WDEN> bit after a powerup.

The duration of the watchdog timeout interval is programmable through the WDT[3:0] bits (See also Table 13: SPI CONTROL REGISTERS (ALL SPI control registers have Read/Write Access and default to "0" after power-on or hard reset). The timing is given in Table 12 below.

Table 12. WATCHDOG TIMEOUT INTERVAL AS FUNCTION OF WDT[3:0]

Index	WDT[3:0]	$t_{WDTO}$ (ms)	Index	WDT[3:0]	$t_{WDTO}$ (ms)
0	0000	32	8	1000	288
1	0001	64	9	1001	320
2	0010	96	10	1010	352
3	0011	128	11	1011	384
4	0100	160	12	1100	416
5	0101	192	13	1101	448
6	0110	224	14	1110	480
7	0111	256	15	1111	512

SPI INTERFACE

The serial peripheral interface (SPI) allows an external microcontroller (Master) to communicate with AMIS-30542. The implemented SPI block is designed to interface directly with numerous micro-controllers from several manufacturers. AMIS-30542 acts always as a Slave and can't initiate any transmission. The operation of the device is configured and controlled by means of SPI registers which are observable for read and/or write from the Master.

SPI Transfer Format and Pin Signals

During a SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line (CLK) synchronizes shifting and sampling of the information on the two serial data lines (DO and DI).

DO signal is the output from the Slave (AMIS-30542), and DI signal is the output from the Master. A chip select line ( $\overline{CS}$ ) allows individual selection of a Slave SPI device in a multiple-slave system. The  $\overline{CS}$  line is active low. If AMIS-30542 is not selected, DO is pulled up with the external pull up resistor. Since AMIS-30542 operates as a Slave in MODE 0 (CPOL = 0; CPHA = 0) it always clocks data out on the falling edge and samples data in on rising edge of clock. The Master SPI port must be configured in MODE 0 too, to match this operation. The SPI clock idles low between the transferred bytes.

The diagram below is both a Master and a Slave timing diagram since CLK, DO and DI pins are directly connected between the Master and the Slave.

Figure 18. Timing Diagram of a SPI Transfer

NOTE: At the falling edge of the eight clock pulse the data-out shift register is updated with the content of the addressed internal SPI register. The internal SPI registers are updated at the first rising edge of the AMIS-30542 system clock when  $\overline{CS}$  = High

Transfer Packet:

Serial data transfer is assumed to follow MSB first rule. The transfer packet contains one or more bytes.

Figure 19. SPI Transfer Packet

Byte 1 contains the Command and the SPI Register Address and indicates to AMIS-30542 the chosen type of operation and addressed register. Byte 2 contains data, or

sent from the Master in a WRITE operation, or received from AMIS-30542 in a READ operation.

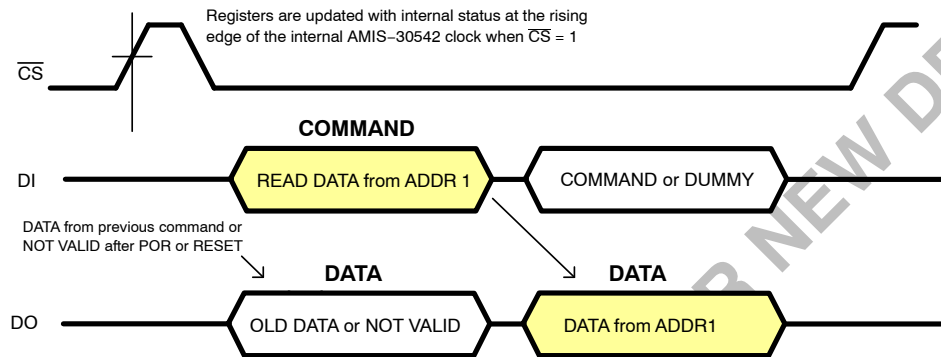

Two command types can be distinguished in the communication between master and AMIS-30542:

- READ from SPI Register with address ADDR[4:0]:  
CMD2 = “0”
- WRITE to SPI Register with address ADDR[4:0]:  
CMD2 = “1”

**READ Operation**

If the Master wants to read data from Status or Control Registers, it initiates the communication by sending a

READ command. This READ command contains the address of the SPI register to be read out. At the falling edge of the eight clock pulse the data-out shift register is updated with the content of the corresponding internal SPI register. In the next 8-bit clock pulse train this data is shifted out via DO pin. At the same time the data shifted in from DI (Master) should be interpreted as the following successive command or dummy data.

**Figure 20. Single READ Operation where DATA from SPI Register with Address 1 is Read by the Master**

All 4 Status Registers (see SPI Registers) contain 7 data bits and a parity check bit. The most significant bit (D7) represents a parity of D[6:0]. If the number of logical ones in D[6:0] is odd, the parity bit D7 equals “1”. If the number of logical ones in D[6:0] is even then the parity bit D7 equals “0”. This simple mechanism protects against noise and increases the consistency of the transmitted data. If a parity check error occurs it is recommended to initiate an additional READ command to obtain the status again.

Also the Control Registers can be read out following the same routine. Control Registers don't have a parity check.

The CS line is active low and may remain low between successive READ commands as illustrated in Figure 22. There is however one exception. In case an error condition is latched in one of Status Registers (see SPI Registers) the ERR pin is activated. (See Section Error Output). This signal flags a problem to the external microcontroller. By reading the Status Registers information about the root cause of the problem can be determined. After this READ operation the Status Registers are cleared. Because the Status Registers and ERR pin (see SPI Registers) are only updated by the internal system clock when the CS line is high, the Master

should force CS high immediately after the READ operation. For the same reason it is recommended to keep the CS line high always when the SPI bus is idle.

**WRITE Operation**

If the Master wants to write data to a Control Register it initiates the communication by sending a WRITE command. This contains the address of the SPI register to write to. The command is followed with a data byte. This incoming data will be stored in the corresponding Control Register after CS goes from low to high! AMIS-30542 responds on every incoming byte by shifting out via DO the data stored in the last received address.

It is important that the writing action (command – address and data) to the Control Register is exactly 16 bits long. If more or less bits are transmitted the complete transfer packet is ignored.

A WRITE command executed for a read-only register (e.g. Status Registers) will not affect the addressed register and the device operation.

Because after a power-on-reset the initial address is unknown the data shifted out via DO is not valid.

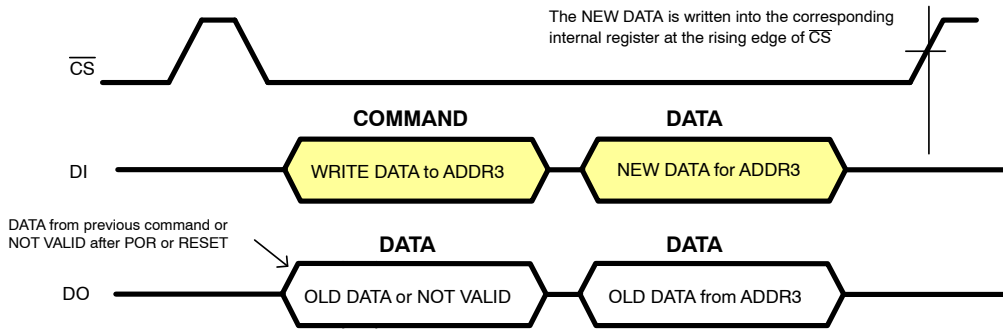

Figure 21. Single WRITE Operation Where DATA from the Master is Written in SPI Register with Address 3

**Examples of combined READ and WRITE Operations**

In the following examples successive READ and WRITE operations are combined. In Figure 22 the Master first reads the status from Register at ADDR4 and at ADDR5 followed

by writing a control byte in Control Register at ADDR2. Note that during the write command the old data of the pointed register is returned at the moment the new data is shifted in

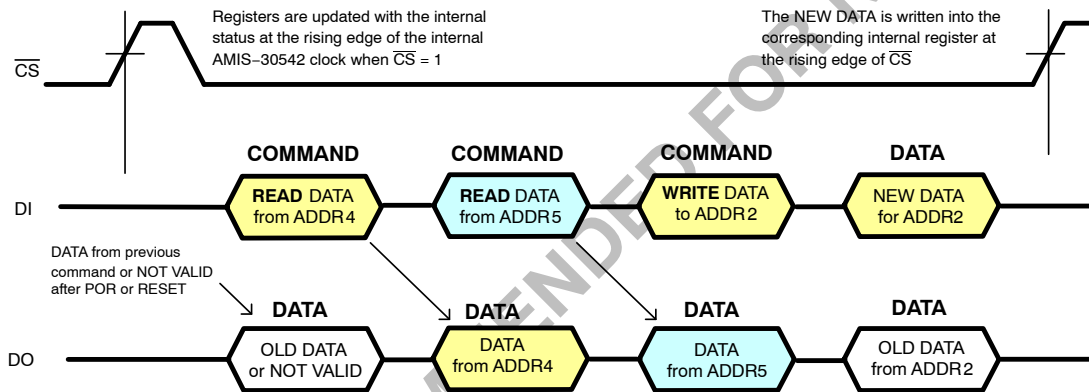

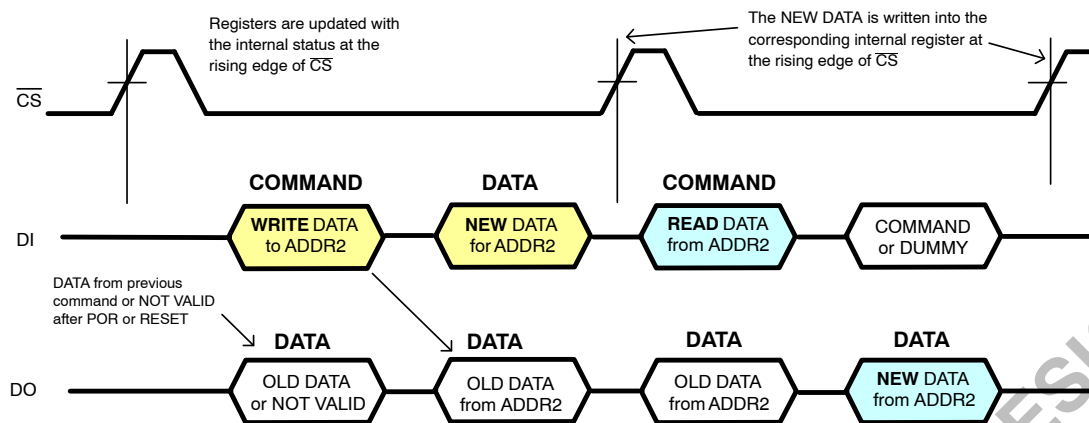

Figure 22. 2 Successive READ Commands Followed by a WRITE Command

After the write operation the Master could initiate a read back command in order to verify the data correctly written as illustrated in Figure 23. During reception of the READ command the old data is returned for a second time. Only after receiving the READ command the new data is

transmitted. This rule also applies when the master device wants to initiate an SPI transfer to read the Status Registers. Because the internal system clock updates the Status Registers only when  $\overline{CS}$  line is high, the first read out byte might represent old status information.

**Figure 23. A WRITE Operation Where DATA from the Master is Written in SPI Register with Address 2 Followed by a READ Back Operation to Confirm a Correct WRITE Operation**

NOTE: The internal data-out shift buffer of AMIS-30542 is updated with the content of the selected SPI register only at the last (every eight) falling edge of the CLK signal (see SPI Transfer Format and Pin Signals). As a result, new data for transmission cannot be written to the shift buffer at the beginning of the transfer packet and the first byte shifted out might represent old data.

**Table 13. SPI CONTROL REGISTERS** (All SPI control registers have Read/Write Access and default to “0” after power-on or hard reset)

Address	Content	Structure							
		Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
		Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W
WR (00h)	Data	WDEN	WDT[3:0]			-	-	-	-
CR0 (01h)	Data	SM[2:0]			CUR[4:0]				
CR1 (02h)	Data	DIRCTRL	NXTP	-	-	PWMF	PWMJ	EMC[1:0]	
CR2 (03h)	Data	MOTEN	SLP	SLAG	SLAT	-	-	-	-
CR2 (08h)	Data	M[1:0]		StrB[1:0]		-	StrC	StrE[1:0]	

Where:

R/W Read and Write access

Reset: Status after power-On or hard reset

Table 14. SPI CONTROL PARAMETER OVERVIEW

Symbol	Description	Status		Value
DIRCTRL	Controls the direction of rotation (in combination with logic level on input DIR)	<DIR> = 0	<DIRCTRL> = 0	CW motion (Note 15)
			<DIRCTRL> = 1	CCW motion (Note 15)
		<DIR> = 1	<DIRCTRL> = 0	CCW motion (Note 15)
			<DIRCTRL> = 1	CW motion (Note 15)
NXTP	Selects if NXT triggers on rising or falling edge	<NXTP> = 0	Trigger on rising edge	
		<NXTP> = 1	Trigger on falling edge	
EMC[1:0]	Turn On – Turn-off Slopes of motor driver (Note 14)	00	Very Fast	
		01	Fast	
		10	Slow	
		11	Very Slow	
SLAT	Speed load angle transparency bit	<SLAT> = 0	SLA is transparent	
		<SLAT> = 1	SLA is NOT transparent	
SLAG	Speed load angle gain setting	<SLAG> = 0	Gain = 0.5	
		<SLAG> = 1	Gain = 0.25	
PWMF	Enables doubling of the PWM frequency (Note 14)	<PWMF> = 0	Default Frequency	
		<PWMF> = 1	Double Frequency	
PWMJ	Enables jittery PWM	<PWMJ> = 0	Jitter disabled	
		<PWMJ> = 1	Jitter enabled	
SM[2:0]	Stepmode	000	1/32 Micro – Step	
		001	1/16 Micro – Step	
		010	1/8 Micro – Step	
		011	1/4 Micro – Step	
		100	Compensated Half Step	
		101	Uncompensated Half Step	
		110	Full Step	
		111	n.a.	
SLP	Enables sleep mode	<SLP> = 0	Active mode	
		<SLP> = 1	Sleep mode	
MOTEN	Activates the motor driver outputs	<MOTEN> = 0	Drivers disabled	
		<MOTEN> = 1	Drivers enabled	
M[1:0]	PWM Mode Control	00	Default control	
		01	DCMin Mode 1	
		10	DCMin Mode 1'	
		11	DCMin Mode 2	
StrB[1:0]	PWM Strobe B Control: DON mask comparator time (Note 16)	00	4 PWM clock cycles	
		01	8 PWM clock cycles	
		10	12 PWM clock cycles	
		11	19 PWM clock cycles	
StrC	PWM Strobe C Control: Switch time top/bottom regulation	<StrC> = 0	86% duty cycle PWM regulator	
		<StrC> = 1	75% duty cycle PWM regulator	
StrE[1:0]	PWM Strobe E Control: Compensation bridge active time (Note 16)	00	4 PWM clock cycles	
		01	8 PWM clock cycles	
		10	12 PWM clock cycles	
		11	19 PWM clock cycles	

14. The typical values can be found in Table 5: DC Parameters and in Table 6: AC parameters

15. Depending on the wiring of the motor connections

16. The duration is depending on the selected PWM frequency
