Chipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

AC/DC Drivers

PWM Control IC

BM1P107FJ

● **General**

   The PWM control IC for AC/DC "BM1P107FJ" provides an optimum system for all products that include an electrical outlet.

   A built-in start circuit that withstands 650 V helps to keep power consumption low. Both isolated and non-isolated versions are supported, making for simpler design of various types of low-power converters. Switching MOSFET and current detection resistors are external devices, thus achieving a higher degree of freedom in power supply design. The switching frequency is set as fixed. Since current mode control is used, a current limit is imposed in each cycle, and excellent performance is demonstrated in bandwidth and transient response. With a light load, frequency is reduced and higher efficiency is realized. A frequency hopping function is also built in, contributing to low EMI.

   Also on chip are soft start and burst functions, a per-cycle overcurrent limiter, VCC overvoltage protection, overload protection, and other protection functions.

● **Basic Specifications**

- Operating power supply voltage range:　VCC 8.9 V to 26.0 V
  　　　　　　　　　　　　　　　　　VH:　　to 600 V
- Operating current:　　　Normal:　0.60 mA　(Typ.)
  　　　　　　　　　Burst mode: 0.35 mA (Typ.)
- Oscillation frequency:　BM1P107FJ:　100 kHz　(Typ.)

- Operating temperature range:　　　　-40°C to +85°C

● **Features**
- PWM frequency:　100 kHz
- PWM current mode method
- Frequency hopping function
- Burst operation during light load / Frequency reduction function
- 650 V start circuit
- VCC pin undervoltage protection
- VCC pin overvoltage protection
- CS pin open protection
- CS pin Leading-Edge-Blanking function
- Per-cycle overcurrent limiter function
- Overcurrent limiter with AC voltage compensation function
- Soft start function
- Secondary overcurrent protection circuit

● **Package**

SOP-J8　　4.90 mm × 6.00 mm × 1.65 mm　pitch 1.27 mm

● **Description of application operations in blocks**

(1)   Start circuit (VH pin: 8 pin)

This IC has a built-in start circuit (withstands 650 V). This enables both low standby mode power and high-speed startup.

This start circuit operates only at startup. The current flow when operating is shown in Figure 5.

After startup, the power consumed is only for the idling current I_{START3} (typ = 10 uA).

ex) When Vac = 100 V, power consumption is from start circuit only
PVH = 100 V*√2*10 uA = 1.41 mW

ex) When Vac = 240 V, power consumption is from start circuit only
PVH = 240 V*√2*10 uA = 3.38 mW

Startup time is determined based on the inflow current for the VH pin and the capacitance for the VCC pin.

Startup time reference values are shown in Figure 6. For example, when C_{VCC} = 10 uF, startup takes about 0.07 seconds.

When the VCC pin has been shorted by GND, the ISTART1 current in Figure 5 flows.

When the VH pin has been shorted by GND, a large current flows to GND from the VH line. To prevent this, insert resistor R_{VH} (5 kΩ ~ 60 kΩ) to limit the current between the VH line and the VH pin of the IC.

When the VH pin is shorted, the power of VH^2/R_{VH} is applied to the resistor. Therefore, select a resistor size that is able to tolerate this amount of power.

If one resistor is not enough for the allowable power, connect two or more resistors in series.
Figure 4. Block Diagram of Start Circuit
Figure 5. Start Current vs VCC Voltage
(* Start current flows from the VH pin.)

The operating waveform at startup is as follows.
Figure 6. Startup Time (Reference Value)
(C_{VCC} is capacitance for the VCC pin.)

6/26
TSZ02201-0F2F0A200170-1-2
2.Oct.2013.Rev.001

The operating waveform at startup is shown in Figure 7.
Figure 7. Operating Waveform at Startup

A: VH voltage is applied when plugged into the outlet. At that time, charging starts from the VH pin via the start circuit to the VCC pin.
   At that time, VCC < V_{SC} (typ = 0.8 V), so the VH input current is limited to ISTART1 by the VCC pin short protection function.

B: Since VCC voltage > V_{SC} (typ = 0.8 V), VCC short protection is cancelled and current flow is from the VH input current.

C: Since VCC voltage > V_{UVLO1} (typ = 13.5 V), the start circuit is stopped and the VH input current flow is only I_{START3} (typ = 10 uA).
   When switching starts, secondary output begins to increase, but since secondary output is low, the VCC pin voltage is reduced. The drop rate of VCC is determined by the consumption current between the VCC pin capacitor and the IC and by the load current connected to the VCC pin. (V/t = Cvcc/Icc)

D: Since secondary output has risen to a constant voltage, voltage is applied from the auxiliary winding to the VCC pin, and VCC voltage is stabilized.

(2) Startup sequences (soft start operation, light load operation, auto recovery operation during overload protection)
Startup sequences are shown in Figure 8.
See the sections below for detailed descriptions.
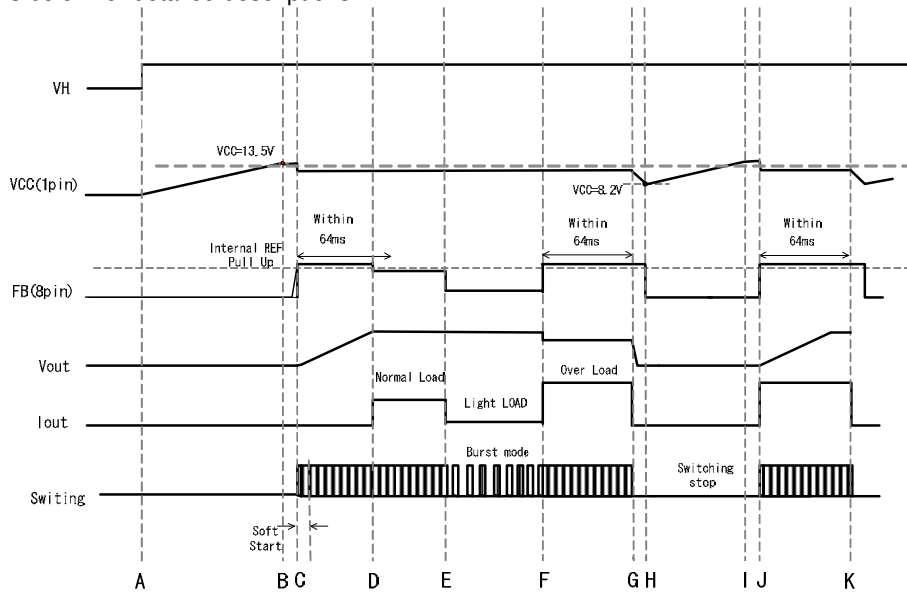

Figure 8. Startup Sequence Time Chart

A: Voltage is applied to the input voltage (VH) pin (pin 8).
B: The VCC pin (pin 6) voltage rises, and when VCC $>$ V$_{UVLO1}$ (13.5 V typ) this IC starts to operate.
   When protection functions (VCC, CS, FB pin, temperature) are judged as normal, switching operation begins.
   At this time, the VCC pin (pin 6) consumption current necessarily causes the VCC pin voltage to drop.
   When VCC $<$ V$_{UVLO2}$ (8.2 V typ), switching operation stops by VCC UVLO function. For that, set VCC capacitor to finish start-up before VCC<V$_{UVLO2}$(8.2V.typ)
C: With the soft start function, excessive rises in voltage and current are prevented by adjusting the voltage level of the CS pin (pin 3). During a soft start, the IC changes the overcurrent detection voltage from V$_{CC\_SS1}$ to V$_{CC\_SS4}$ to prevent overshoot of the output voltage. V$_{CC\_SS1}$ is described in Table 2 below.

Table 2   Overcurrent Detection Voltage at Startup

Soft start	Vlim1
Start ~ 0.5 ms	0.10 V (12%)
0.5 ms ~1 ms	0.15 V (25%)
1 ms ~2 ms	0.20 V (50%)
2 ms ~4 ms	0.30 V (75%)
4 ms ~	0.500 V (100%)

D: When the switching operation starts, the secondary output voltage VOUT rises.
   After switching has started, set the output voltage to within T$_{FOLP}$ (64 ms typ) to become the rated voltage.
E: When there is a light load, burst operation suppresses power consumption.
F: When there is an overload, the FB pin (pin 2) voltage becomes greater than V$_{FOLP1A}$ to reduce the output voltage.
G: If the FB pin (pin 2) voltage exceeds V$_{FOLP1A}$ for T$_{FOLP}$ (64 ms typ) or longer, the overload protection circuit stops the switching operation. For that, set to finish the start-up time within TFOLP (64 ms typ).
   When the FB pin (pin 2) voltage exceeds V$_{FOLP1B}$, the IC's internal timer T$_{FOLP}$ (64 ms typ) is reset.
H: When VCC voltage becomes VCC < V$_{UVLO2}$ (8.2 V typ), the start circuit operates and VCC charging is started.

I: When VCC voltage becomes VCC> V$_{UVLO1}$ (13.5 V typ), the start circuit stops charging VCC.
J: Same as F
K: Same as G
Startup waveforms are shown as reference examples in Figure 9 and Figure 10.
Figure 9. Waveform of No-load Startup

Figure 10. Waveform of High-load Startup

(3) VCC pin protection function

This IC includes a VCC pin under voltage protection function VCC UVLO (Under Voltage Protection) and overvoltage protection function VCC OVP (Over Voltage Protection).

The VCC UVLO function and VCC OVP function prevent damage to the switching MOSFET that can occur when the VCC voltage drops or becomes excessive.

(3-1) VCC UVLO and VCC OVP functions

VCC UVLO is an auto recovery type comparator with voltage hysteresis. For VCC OVP, the BM1P067FJ has an auto recovery type comparator.

After VCCOVP operation detects, switching operation re-start when VCC<V_{OVP2} (typ=23.5V).

The operation is shown in Figure 11.

A mask time T_{LATCH} (typ = 100 us) is built in for VCC OVP to prevent miss-detection. The detection is performed when the VCC pin (pin 6) voltage continues to exceed V_{OVP1} (typ = 27.5 V) for T_{LATCH} (typ = 100 us).

This function masks surges or the like that occur at the pin. (See section (7) below.)
Figure 11. VCC UVLO / OVP Time Chart

9/26
TSZ02201-0F2F0A200170-1-2
2.Oct.2013.Rev.001

A: Voltage is applied to the VH pin (pin 8) and voltage at the VCC pin (pin 6) starts to rise.

B: When VCC pin (pin 6) voltage > V_{UVLO1}, the VCC UVLO function is canceled and the DC/DC operation starts. Then VCC start-up circuit stops charging.

C: When VCC pin (pin 6) voltage < V_{UVLO2}, the VCC UVLO function is operated and the DC/DC operation stops. Then VCC start-up circuit starts charging.

D: When VCC pin (pin 6) voltage > V_{UVLO1}, the VCC UVLO function is canceled and the DC/DC operation starts. Then VCC start-up circuit stops charging.

E: After finishing start-up, VCC pin voltage is stable as secondary output voltage is stable.

F: VCC pin voltage rises

G: When VCC pin (pin 6) voltage > V_{OCP} status continues for T_{LATCH} (typ = 100us), switching operation is stopped by the VCC OVP function.

H: When VCC pin voltage < V_{OVP2}, VCCOVP function is released, and the switching operation re-starts.

I: When VCC pin voltage < V_{UVLO2}, VCCUVLO function operates, and switching operation stops.

J: When VCC pin (pin 6) voltage > V_{UVLO1}, the VCC UVLO function is canceled and the DC/DC operation starts.

K: The same as I.

L: The same as J.

M: The same as K.

N: High voltage line VH is reduced. Then VCC pin voltage drops because IC cannot charge the power to VCC pin.

O: When VCC < V_{UVLO2}, the VCC UVLO function operates.

P: When VCC > V_{UVLO}, start-up circuit stops, and the switching operation re-starts.

・Capacitance value of VCC pin
 To ensure stable operation of the IC, set the VCC pin capacitance value to 10 uF or above.
 If the capacitor for the VCC pin is too large, it will delay the response of the VCC pin to secondary output. In cases where the transformer has a low degree of coupling, a large surge can be generated at the VCC pin, which may damage the IC. In such cases, insert a resistance of 10 Ω to 100 Ω on a bus between the diode and capacitor after the auxiliary winding. As for constants, perform a waveform evaluation of the VCC pin and enter settings that will prevent any surge at the VCC pin from exceeding the absolute maximum rating for the VCC pin.

・VCC OVP voltage protection settings for increased secondary output

The VCC pin voltage is determined by the secondary output and the transformer ratio (Np:Ns).
Accordingly, when secondary output has become large, it can be protected by VCC OVP.
The VCC OVP protection settings are as follows.
Figure 12   VCC OVP Settings

 This is determined by VCC voltage = Vout x Nb/Ns.
 (Vout: Secondary output, Nb: auxiliary winding turns, Ns: secondary winding turns).

When secondary output voltage rises 30% high, and protection is desired, set the number of winding turns so that 1.3 x Vout x (Nb/Ns) > V_{OVP1}.
For VCC OVP protection, since there is the T_{LATCH} (typ = 100 us) blanking time, VCC OVP protection cannot be detected for instantaneous surges at the VCC pin.
However, VCC OVP is detected when the VCC pin voltage has become higher than V_{OVP1} for at least the T_{LATCH} period, such as due to the impact of a low degree of transformer couplings, so an application evaluation should be done to check this before setting VCC OVP.

(4) DC/DC driver (PWM comparator, frequency hopping, slope compensation, OSC, burst)

(4-1) PWM basic operations
Figure 13 shows a PWM basic block diagram and Figure 14 illustrates PWM basic operations.

Figure 13. Block Diagram of IC Internal PWM Operations

Figure 14. PWM Basic Operations

A: A SET signal is output from the oscillator in the IC, and the MOSFET is turned ON.
   At that time, the capacitance between the MOSFET drain and source becomes discharged, and noise is generated at the CS pin.
   This noise is called the leading edge.
   This IC has a built-in filter for this noise. (See (5).)
   As a result of this filter and delay time, the minimum pulse width of the IC is 400 ns (typ).
   Afterward, current flow to the MOSFET and the Vcs = Rs * Ip voltage is applied to the CS pin.
B: When CS pin voltage rises to become greater than the FB pin voltage/Gain (typ = 4) or the overcurrent detection voltage Vcs, the RESET signal is output and OUT is turned off.
C: There is a delay time Tondelay between time point B and actual turn-off. This time is the result of differences in maximum power that occur based on the AC voltage. This IC includes a function that suppresses these differences. (See (4-4).)
D: The energy that accumulates in the transformer during Ton status is discharged to the secondary side, and the drain voltage starts to oscillate freely based on the transformer Lp value and the MOSFET Cds (drain-source capacitance).
E: Since the switching frequency within the IC is predetermined, SET signal output from the internal oscillator occurs for a set period starting from point A, and the MOSFET is turned on.

(4-2) Frequency operations
Figure 15. PWM Operations in IC

The PWM frequency is generated by the OSC block (internal oscillator) in Figure 15.
This oscillator has a switching frequency hopping function and the switching frequency changes such as is shown in Figure 16.
The fluctuation cycle is 125 Hz. Due to this frequency hopping function, the frequency spectrum is dispersed and the frequency spectrum peak is lowered. This increases the margin for EMI testing.
Figure 16. Frequency Hopping Function

In Figure 16, the duty is calculated as Ton * Switching frequency * 100. The maximum duty value is Dmax (typ = 75%).
Since the PWM current mode method is being used, if the duty exceeds 50% sub harmonic oscillation may occur. 22 mV/us slope compensation is built in as a countermeasure to this.
To reduce power consumption when there is a light load, a burst mode circuit and frequency reduction circuit are built in. These operations are illustrated in Figure17. As shown in this figure, frequency fluctuates according to the FB voltage. If the FB voltage is in the range shown for mode2, switching loss is reduced by reducing internal oscillations based on the FB voltage.

TSZ02201-0F2F0A200170-1-2
2.Oct.2013.Rev.001
Figure 17. Operation with FB pin voltage

・mode1: Burst operation
・mode2: Frequency reduction operation (reduces maximum frequency.)
・mode3: Fixed frequency operation (operates at maximum frequency.)
・mode4: Overload operation (overload status is detected and pulse operation is stopped.)

(4-3) Overcurrent detection operation

R_{FB} (30 kΩ.typ) is used as pull-up resistance for the FB pin with regard to the internal power supply (4.0 V).
When the load of the secondary output voltage (secondary load power) changes, the photo-coupler current changes, and so the FB pin voltage also changes.
FB voltage VFB is determined by the equation FB voltage = 4 V - I_{FB}. (I_{FB}: photo coupler current)
For example, when the load becomes heavier, the FB current is reduced, so the FB voltage rises.
When the load becomes lighter, the FB current is increased, so the FB voltage drops.
In this way, secondary voltage is monitored by the FB pin.

As the FB pin voltage is monitored, if the load becomes lighter (if FB voltage drops), a burst mode operation or frequency reduction operation is executed.
Figure 18 shows the CS detection voltage with regard to FB voltage.
Figure 18   FB Voltage and CS Voltage Characteristics

When FB voltage is less than 2.0 V or when the CS voltage exceeds the FB voltage / Gain (typ = 4), the MOSFET is turned off.
(See time point C in Figure 14.)
When the FB voltage exceeds 2.0 V, the CS voltage = Vcs + Kcs * Ton. Kcs * Ton depends on AC voltage compensation.
(See 4-4.)
Therefore, peak current Ip is determined as Ip = Vcs1 / Rs.
The current value for the MOSFET should be set with a margin with regard to the Ip value obtained from this formula.

Maximum power is determined as Pmax = 1/2 x Lp x Ip^2 x Fsw. (Lp: primary inductance value, Ip: primary peak current, Fsw: switching frequency)

Vcs1 is determined as Vcs1 = Vcs (typ = 0.4 V) + Kcs (typ = 20) * Ton + Vdelay.
Vdelay is the amount of CS voltage increase during the delay time Rondelay between B and C in Figure 14.
This is calculated as Vdelay = Vin / Lp * Tondelay * Rs.

(4-4) AC voltage dependent compensation of overcurrent limiter
This IC has an AC voltage compensation function on chip. This function performs compensation for AC voltage by increasing the level of the overcurrent limiter over time. In the equation below, (A) and (B) are assigned values similar to those for AC 100 V and AC 200 V to perform compensation.

$$\text{Vcs1} = \text{Vcs (typ = 0.4 V)} + \underbrace{\text{Kcs (typ = 20) *Ton}}_{(A)} + \underbrace{\text{Vdelay}}_{(B)}$$

These operations are shown in Figures 19, 20, and 21.
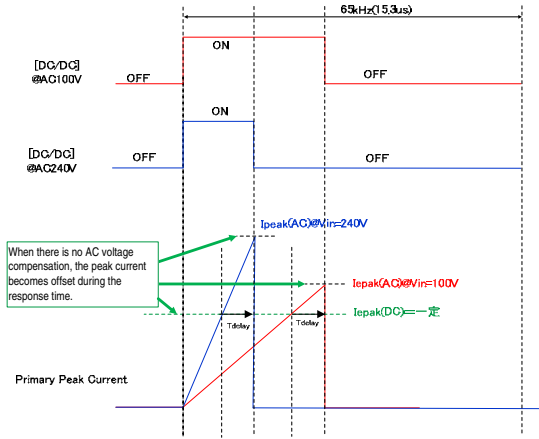

Figure 19.   Without AC Voltage Compensation Function
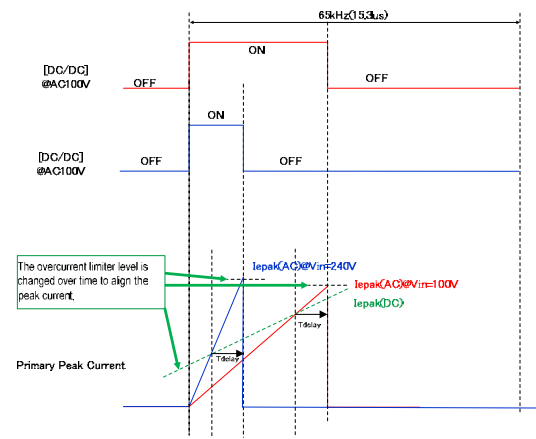

Figure 20.   With AC Voltage Compensation Function

Primary peak current that flows during overload mode is defined as follows.

Primary peak current $\underline{I_{peak} = V_{cs}/R_s + Kcs * Ton/R_s + V_{in}/L_p * T_{ondelay}}$

V_{cs}:   Overcurrent limiter voltage in IC
R_s: Current detection resistor
V_{in}:   Input DC voltage
L_p: Primary peak current
$T_{ondelay}$: Delay time after overcurrent limiter detection
Figure 21. Overcurrent Limiter Voltage

(6) L.E.B period

When the driver MOSFET is turned on, a surge current is generated at time point A in Figure 14.
At that time, the CS voltage (pin 4) rises, which may cause detection errors in the overcurrent limiter circuit.
To prevent these detection errors, the OUT pin in this IC is switched from low to high and the CS voltage (pin 4) is masked for 250 ns by the built-in L.E.B. function (Leading Edge Blanking function).
This blanking function can reduce the CS pin noise filter for the noise that is generated when switching the OUT pin from low to high.
However, if the CS pin noise does not stay within this 250 ns period, an RC filter should be applied to this pin, such as is shown in Figure 22. At this time, a delay time occurs due to the RC filter when the CS pin is detected.
Even if there is no filter, attachment of R_{CS} as a surge countermeasure is recommended.
The recommended resistance for Rcs is 1 kΩ. When a filter ring is desired, use Ccs to adjust for this resistance.
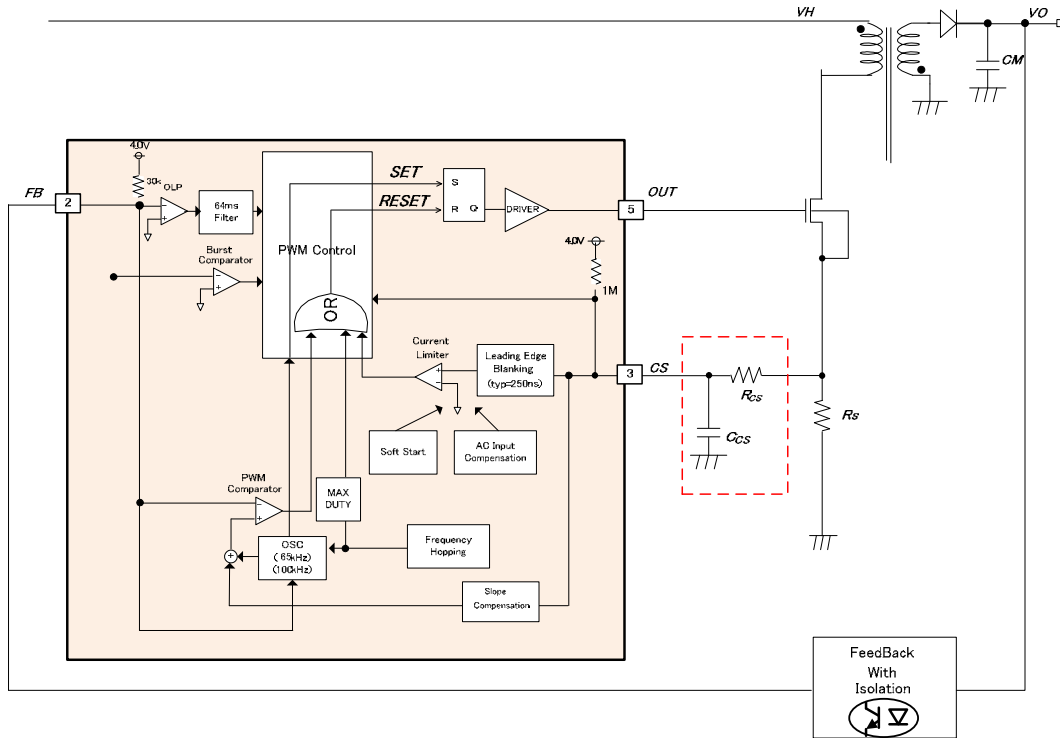

Figure22. Circuits Peripheral to the CS Pin

(6) CS pin open protection

When the CS pin (pin 4) has become an open pin, transient heat (due to noise, etc.) occurs in the IC, which may become damaged.
An open protection circuit has been built in to prevent such damage. (Auto recovery protection)
Figure 23. CS Pin Peripheral Circuit

(7) Output overload protection function (FB OLP comparator)

As is shown in mode4 of Figure 17, when the FB pin voltage rises to above a certain value, it is called an overload condition.

The output overload protection function stops switching operations when mode4 has an overload condition.

During an overload condition, the output voltage drops and so current no longer flows to the photo coupler while the FB voltage (pin 2) rises.

When the FB voltage (pin 2) exceeds V_{FOLP1A} (2.8V typ) continuously for T_{FOLP2} (64ms typ), it is judged as an overload condition and switching is stopped.

While the FB pin (pin 2) exceeds V_{FOLP1A}(2.8V typ), if the FB pin (pin 2) voltage drops below V_{FOLP1B}(2.6V typ) during the T_{FOLP}(64 ms typ) period, the overload protection timer is reset. Switching operation are performed during the T_{FOLP}(64ms typ) period. At startup, the FB pin (pin 2) voltage is pulled up by a resistance to the IC internal voltage, and operations start when the voltage reaches V_{FOLP1A}(2.8V typ) or above. Therefore, at startup the start time of secondary output voltage must be set so that the FB voltage (pin 2) drops to V_{FOLP1B}(2.6V typ) or below within the T_{FOLP}(64 ms typ) period.

Once FBOLP is detected, the switching operation stops, and VCC voltage falls down because secondary output voltage falls down. When VCC voltage is lower than V_{UVLO2}(8.2V.typ), IC is reset, and IC starts by starter circuit shown in (1). The switching stop time is calculated by VCC pin voltage and VCC capacitor and Icc current

Stop time : Tstop   Tstop=Cvcc*(VCC－Vuvlo2) / Icc
Figure 24. Overload Protection (Auto Recovery)

A: Since FB > V_{FOLP1A}, the FBOLP comparator detects an overload.
B: When FB<VFOLP1B within T_{FOLP}（typ=64ms） period, FB overload detection is released, and FBOLP timer is reset.
C: Since FB > V_{FOLP1A}, the FBOLP comparator detects an overload.
D: When the condition at C continues for T_{FOLP} (typ = 64 ms), switching is stopped by the overload protection function. As switching operation stops, VCC pin voltage falls down because output voltage falls down.
E: When VCC pin voltage < VUVLO2, IC is reset by VCC UVLO function, and start-up circuit operates.
F: When VCC pin voltage > VUVLO1, VCC UVLO is released, and switching operation starts.
G: Because secondary output voltage is stable, VCC pin voltage is also stable.

(8-1) OUT pin clamp function

　　To protect the external MOSFET, the high voltage level of the OUT pin (pin 5) is clamped to V$_{OUTH}$ (typ = 12.5 V).
　The VCC pin (pin 6) voltage is raised to prevent MOSFET gate damage. (Shown in Figure25.)

Figure 25. OUT Pin (Pin 5) Schematic

**(8-2) OUT pin driver circuit**

Figure 26. OUT Pin (Pin 5) Driver Circuit

　Switching noise that occurs when OUT is turned on or off may cause EMI-related problems.
In such cases, the MOSFET turn-on time and turn-off time must be delayed.
However, when the turn off time is delayed, switching loss increases.
Figure 26 shows a delay circuit for the OUT pin. In Figure 26, ① is valid during both turn-on and turn-off operations.
② shows a delay in the turn-on only, while turn-off is accelerated.

(9) Caution points for board layout pattern
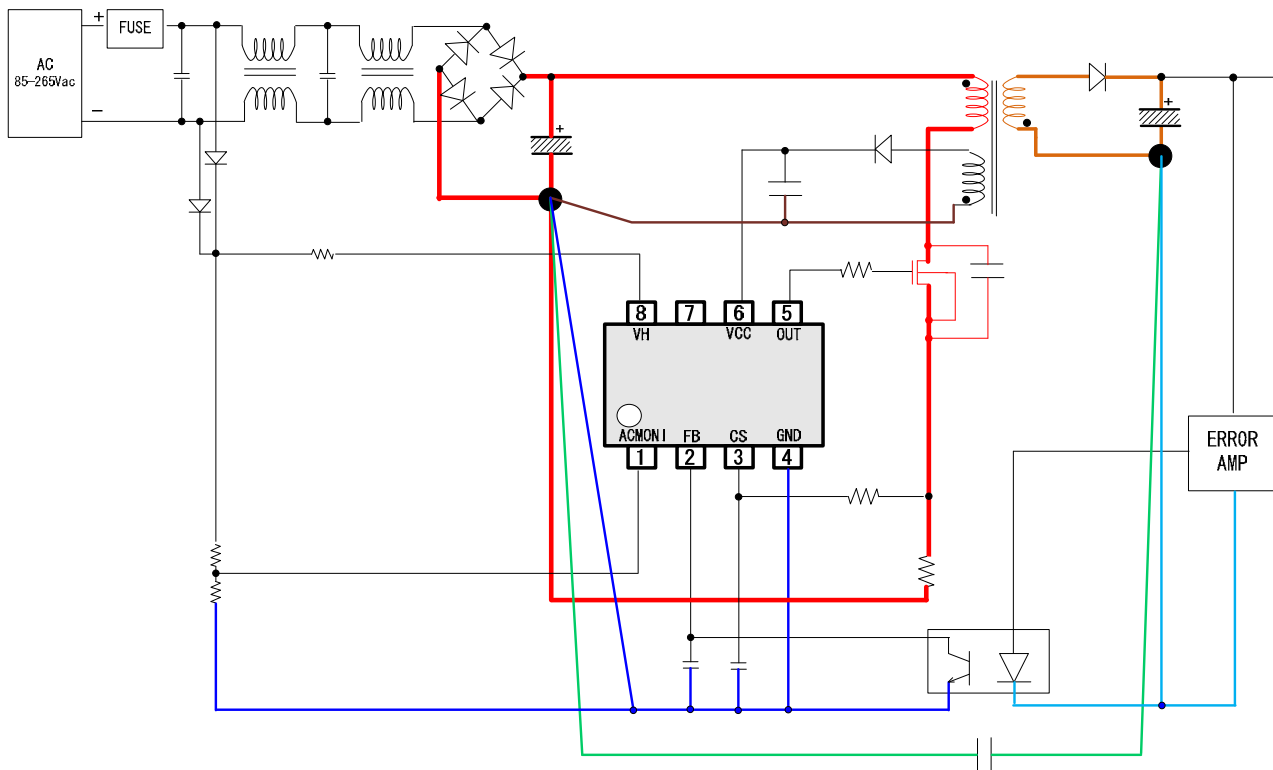

Figure 27. Board Layout Pattern

・Caution points
① The red lines shown in Figure 27 are large current pathways. In the layout, these should be as short as possible since they can cause ringing, dissipation, etc.
Also, any loops that occur in the red line should be made as small as possible in this layout.

② The orange lines in the secondary side of Figure 27 should also be made short and thick like the red lines and should be made with small loops in this layout.

③ Be sure to implement grounding for the red lines, brown lines, blue lines, and green lines.

④ The green lines are pathways for surges on the secondary side to escape to the primary side, and since a large current may flow instantaneously, they should be laid out independently of the red lines and blue lines.

⑤ The blue lines are GND lines for IC control. They do not have any large current flow, but they are susceptible to noise effects, so they should be laid out independently of the red lines, green lines, and brown lines.

⑥ The brown lines are current pathways for the VCC pin. A current flows on these lines during switching, so they should also be laid out independently.

⑦ Do not route any IC control lines directly under the transformer, since they may be affected by magnetic flux.

(Application circuit example)
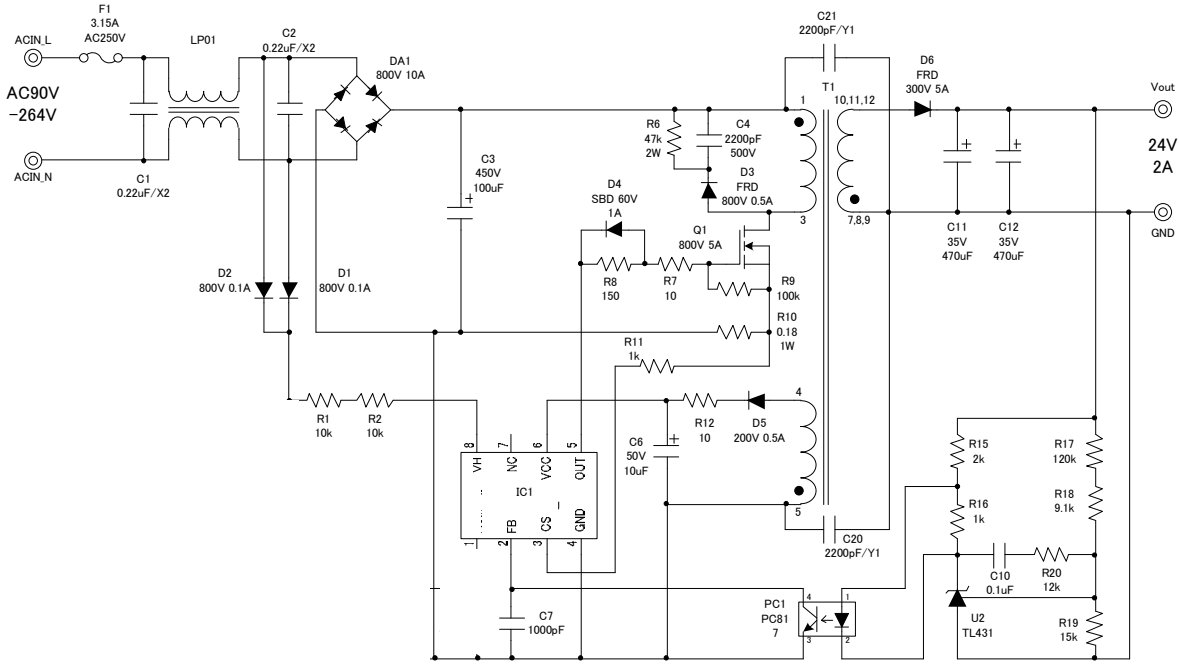

Figure 28. Application Circuit Example

● **Operation modes of protection circuit**
Table 3 lists the operation mode of each protection function.

Table 3. Operation Modes of Protection Circuit

Function	Operation mode
VCC Undervoltage Locked Out	Auto recovery
VCC Overvoltage Protection	Auto recovery (with 100-us timer)
FB Over Limited Protection	Auto recovery (with 64-us timer)
CS OPEN Protection	Auto recovery (with 100-us timer)

● **Sequence**
The sequence for this IC is shown in Figure 29.
A transition to OFF mode occurs under all conditions when VCC exceeds 8.2 V.
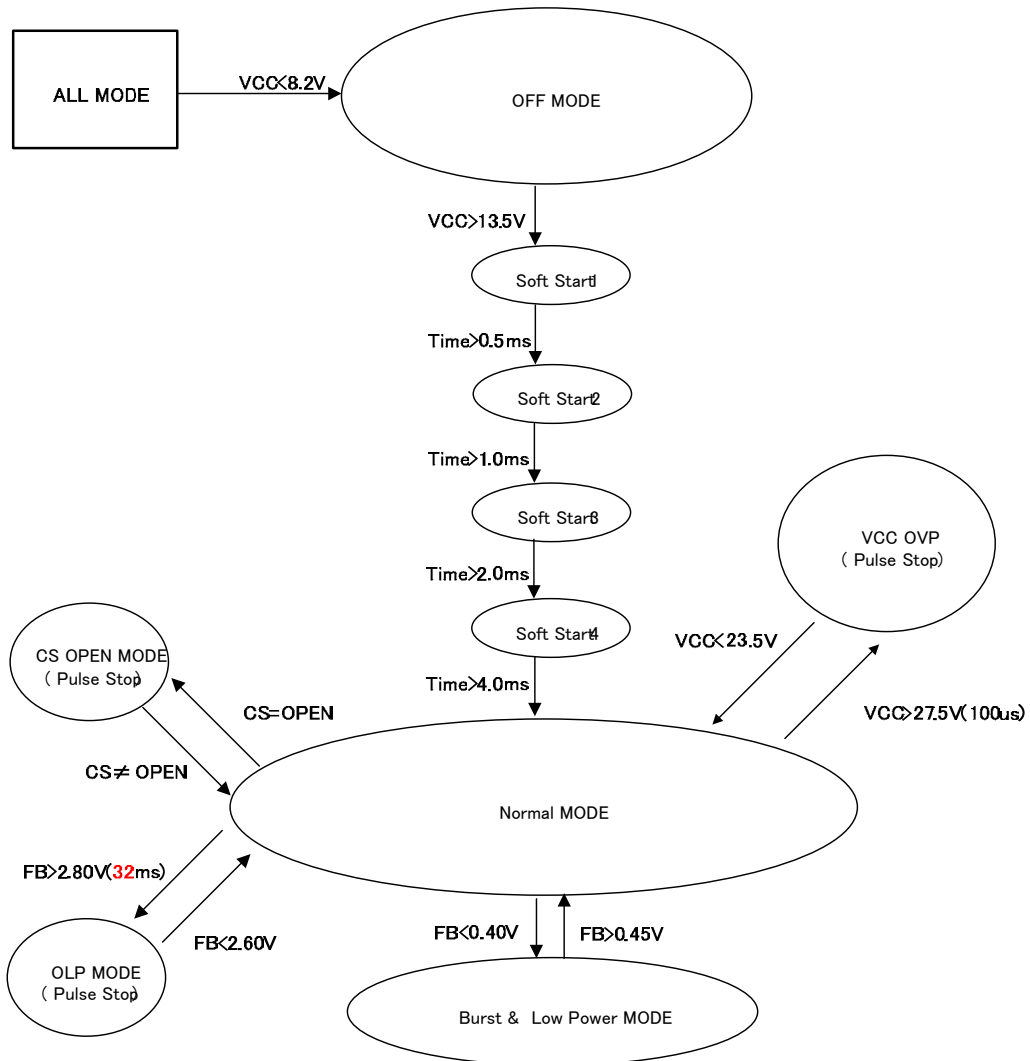

Figure 29. Sequence Diagram

● **Thermal loss**
In the thermal design, set operations for the following conditions.
(The temperature shown below is the guaranteed temperature, so be sure that a margin is taken into account.)

1. Ambient temperature Ta must be 85°C or less.
2. IC loss must be within the allowable dissipation Pd.

The thermal abatement characteristics are follows. (PCB: 70 mm x 70 mm x 1.6 mm, when mounted on glass epoxy substrate)
Figure 30. Thermal Abatement Characteristics

Operational Notes

1. **Reverse Connection of Power Supply**
   Connecting the power supply in reverse polarity can damage the IC. Take precautions against reverse polarity when connecting the power supply, such as mounting an external diode between the power supply and the IC's power supply pins.

2. **Power Supply Lines**
   Design the PCB layout pattern to provide low impedance supply lines. Separate the ground and supply lines of the digital and analog blocks to prevent noise in the ground and supply lines of the digital block from affecting the analog block. Furthermore, connect a capacitor to ground at all power supply pins. Consider the effect of temperature and aging on the capacitance value when using electrolytic capacitors.

3. **Ground Voltage**
   Ensure that no pins are at a voltage below that of the ground pin at any time, even during transient condition.

4. **Ground Wiring Pattern**
   When using both small-signal and large-current ground traces, the two ground traces should be routed separately but connected to a single ground at the reference point of the application board to avoid fluctuations in the small-signal ground caused by large currents. Also ensure that the ground traces of external components do not cause variations on the ground voltage. The ground lines must be as short and thick as possible to reduce line impedance.

5. **Thermal Consideration**
   Should by any chance the power dissipation rating be exceeded the rise in temperature of the chip may result in deterioration of the properties of the chip. The absolute maximum rating of the Pd stated in this specification is when the IC is mounted on a 70mm x 70mm x 1.6mm glass epoxy board. In case of exceeding this absolute maximum rating, increase the board size and copper area to prevent exceeding the Pd rating.

6. **Recommended Operating Conditions**
   These conditions represent a range within which the expected characteristics of the IC can be approximately obtained. The electrical characteristics are guaranteed under the conditions of each parameter.

7. **Inrush Current**
   When power is first supplied to the IC, it is possible that the internal logic may be unstable and inrush current may flow instantaneously due to the internal powering sequence and delays, especially if the IC has more than one power supply. Therefore, give special consideration to power coupling capacitance, power wiring, width of ground wiring, and routing of connections.

8. **Operation Under Strong Electromagnetic Field**
   Operating the IC in the presence of a strong electromagnetic field may cause the IC to malfunction.

9. **Testing on Application Boards**
   When testing the IC on an application board, connecting a capacitor directly to a low-impedance output pin may subject the IC to stress. Always discharge capacitors completely after each process or step. The IC's power supply should always be turned off completely before connecting or removing it from the test setup during the inspection process. To prevent damage from static discharge, ground the IC during assembly and use similar precautions during transport and storage.

10. **Inter-pin Short and Mounting Errors**
    Ensure that the direction and position are correct when mounting the IC on the PCB. Incorrect mounting may result in damaging the IC. Avoid nearby pins being shorted to each other especially to ground, power supply and output pin. Inter-pin shorts could be due to many reasons such as metal particles, water droplets (in very humid environment) and unintentional solder bridge deposited in between pins during assembly to name a few.
