

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

CAT4103

3-Channel Constant-Current RGB LED Driver

Description

The CAT4103 is a 3-channel, linear based constant-current LED driver designed for RGB LED control, requiring no inductor and provides a low noise operation. LED channel currents up to 175 mA are programmed independently via separate external resistors. Low output voltage operation of 0.4 V at 175 mA allows for more power efficient designs across wider supply voltage range. The three LED pins are compatible with high voltage up to 25 V supporting applications with long strings of LEDs.

A high-speed 4-wire 25 MHz serial interface controls each individual channel using a shift register and latch configuration. Output data pins allow multiple devices to be cascaded and programmed via one serial interface with no need for external drivers or timing considerations. The device also includes a blanking control pin (BIN) that can be used to disable all channels independently of the interface.

Thermal shutdown protection is incorporated in the device to disable the LED outputs whenever the die temperature exceeds 150°C.

The device is available in a 16-lead SOIC package.

Features

- 3 Independent Current Sinks Rated to 25 V
- LED Current to 175 mA per Channel Set by Separate External Resistors
- High-speed 25 MHz 4-wire Serial Interface
- Buffered Output Drivers to Ensure Data Integrity
- Cascadable Devices
- Low Dropout Current Source (0.4 V at 175 mA)
- 3 V to 5.5 V Logic Supply
- Thermal Shutdown Protection
- 16-lead SOIC Package
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

Applications

- Multi-color, Intelligent LED, Architectural Lighting
- High-visual Impact LED Signs and Displays
- LCD Backlight

BOUT	15	Blank output pin
VDD	16	Device Supply pin

Pin Function

GND is the ground reference pin for the entire device. This pin must be connected to the ground plane on the PCB.

BIN is the blank input used to disable all channels. When low, all LED channels are enabled according to the output latch content. When high, all LED channels are turned off. This pin can be used to turn all the LEDs off while preserving the data in the output latches.

LIN is the latch data input. On the rising edge of LIN, data is loaded from the 3-bit serial shift register into the output register latch. On the falling edge of LIN the data is latched in the output register and isolated from the state of the serial shift register.

SIN is the serial data input. Data is loaded into the internal register on each rising edge of CIN.

CIN is the serial clock input. On each rising CIN edge, data is transferred from SIN to the internal 3-bit serial shift register.

RSET1 to RSET3 are the LED current set inputs. The current pulled out of these pins will be mirrored in the corresponding LED channel with a gain of 400.

LED1 to LED3 are the LED current sink inputs. These pins are connected to the bottom cathodes of the LED strings. The current sinks bias the LEDs with a current equal to 400 times the RSET pin current. For the LED sink to operate correctly, the voltage on the LED pin must be above 0.4 V. Each LED channel can withstand and operate with voltages up to 25 V.

COUT is a driven output of CIN and can be connected to the next device in the cascade.

SOUT is the output of the 3-bit serial shift register. Connect to SIN of the next device in the cascade. SOUT is clocked on the falling edge of CIN.

LOUT is a driven output of LIN and can be connected to the next chip in the cascade.

BOUT is a driven output of BIN and can be connected to the next chip in the cascade.

VDD is the positive supply pin voltage for the entire device. A small 1 μ F ceramic capacitor is recommended close to the pin.

Application Information

Cascading Multiple Devices

The CAT4103 is designed to be cascaded for driving multiple RGD LEDs. Figure 16 shows three CAT4103 drivers cascaded together. The programming data from the controller travels serially through each device. Figure 15 shows a programming example turning on the following LED channels: BLUE3, GREEN2 and RED1. The programming waveforms are measured from the controller to the inputs of the first CAT4103.

Figure 15. Programming Example

Figure 16. Three Cascaded CAT4103 Devices

Power Dissipation

The power dissipation (P_D) of the CAT4103 can be calculated as follows:

$$P_D = (V_{DD} \times I_{DD}) + \Sigma(V_{LEDN} \times I_{LEDN})$$

where V_{LEDN} is the voltage at the LED pin, and I_{LEDN} is the associated LED current. Combinations of high V_{LED} voltage or high ambient temperature can cause the CAT4103 to enter thermal shutdown. In applications where V_{LEDN} is high, a resistor can be inserted in series with the LED string to lower P_D .

Thermal dissipation of the junction heat consists primarily of two paths in series. The first path is the junction to the case (θ_{JC}) thermal resistance which is defined by the package style, and the second path is the case to ambient (θ_{CA}) thermal resistance, which is dependent on board layout. The overall junction to ambient (θ_{JA}) thermal resistance is equal to:

$$\theta_{JA} = \theta_{JC} + \theta_{CA}$$

For a given package style and board layout, the operating junction temperature T_J is a function of the power dissipation P_D , and the ambient temperature, resulting in the following equation:

$$T_J = T_{AMB} + P_D (\theta_{JC} + \theta_{CA}) = T_{AMB} + P_D \theta_{JA}$$

When mounted on a double-sided printed circuit board with two square inches of copper allocated for “heat spreading”, the resulting θ_{JA} is about 74°C/W.

For example, at 60°C ambient temperature, the maximum power dissipation is calculated as follow:

$$P_{Dmax} = \frac{(T_{Jmax} - T_{AMB})}{\theta_{JA}} = \frac{(150 - 60)}{74} = 1.2 \text{ W}$$

Recommended Layout

Bypass capacitor C1 should be placed as close to the IC as possible. RSET resistors should be directly connected to the GND pin of the device. For better thermal dissipation, multiple via can be used to connect the GND pad to a large ground plane. It is also recommended to use large pads and traces on the PCB wherever possible to spread out the heat. The LEDs for this layout are driven from a separate supply (V_{LED+}), but they can also be driven from the same supply connected to V_{DD} .
