

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# Five-Channel Power Supply Supervisors

## FEATURES

- Five-channel supply voltage detection
- 2  $V_{DD}$  inputs allow monitoring of +5.0V, +3.3V, +3.0V, +2.5V or +1.8V supplies
- 3 adjustable voltage inputs allow monitoring supplies > 0.6V
- 70ms minimum reset delay
- Manual reset capability
- Reset signals valid down to  $V_{DD} = 1V$
- Accurate  $\pm < 2\%$  voltage threshold
- Power-supply transients suppressed
- Low 2 $\mu$ A maximum supply current at 5V
- RoHS-compliant MSOP package

## APPLICATIONS

- Telecom & datacom systems
- Routers & servers
- Data storage equipment
- Set-top boxes
- Multi-voltage systems

## DESCRIPTION

The CAT885 is a five-channel power supply supervisory circuit with high reset threshold accuracy and very low power consumption. The device features an open-drain output, active-low function with manual reset to perform basic system reset and monitoring functions for a wide range of electronic products. The CAT885 monitors five system voltages by maintaining a reset output active until all the power supply voltages exceed the specified trip values. The device then maintains the reset output in an active condition until the internal timer times out, which allows the system power supplies to stabilize.

Two of the five voltage detectors are factory set for standard supplies, while the threshold voltages of the third, fourth, and fifth voltage monitors can be adjusted for specific system design requirements using external resistors.

The CAT885 lowers system costs and saves board space by integrating five channels into a single, small MSOP 8-lead package.

**Notes:**

- (1) Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the devices at these or any other conditions outside of those listed in the operational sections of this specification is not implied. Exposure to any absolute maximum rating for extended periods may affect device performance and reliability.
- (2)  $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air.

**OPERATION**

The CAT885 is designed to monitor critical supply voltages in line driven and battery powered microprocessor systems, providing Supply Voltage Supervision, Power On Reset control and Manual Reset Assertion. These features along with excellent threshold accuracy and low power consumption make the CAT885 device suitable for a wide variety of applications needing multi-voltage monitoring.

CAT885 allows users to adjust the minimum voltage sense level for three of the five monitored voltages. For example, the user can adjust the voltage input trip point for V<sub>3MON</sub>, V<sub>4MON</sub> and V<sub>5MON</sub> inputs. This is done by connecting an external resistor divider network to the V<sub>xMON</sub> pin in order to set the trip point to a voltage above 600mV. Resistors R<sub>1</sub> and R<sub>2</sub> in Figure 1 are selected by the formula:  $V_{\text{TRIP}} = 0.6V \times (R_1 + R_2) / R_2$ .

During normal operation, the CAT885 monitors the voltage levels of V<sub>DD</sub>, V<sub>2MON</sub>, V<sub>3MON</sub>, V<sub>4MON</sub>, and V<sub>5MON</sub>. If the voltage on any of these five inputs falls below their respective voltage trip points, a reset is asserted ( $\overline{\text{RST}} = \text{low}$ ) to prevent the microprocessor from operating during a power failure or brownout condition. This reset signal remains low until the voltages exceeds the voltage threshold settings for the reset time delay period t<sub>PD</sub>.

**Figure 1. CAT885 Programming Trip Voltage**

**POWER ON RESET (POR)**

Applying power to the CAT885 activates a POR circuit which activates the reset output (active LOW). At power-up POR prevents the system microprocessor from starting to operate with insufficient voltage and prior to stabilization of the clock oscillator. It ensures that operation is precluded until internal registers are properly loaded, FPGA's have downloaded their configuration data prior and all system power supplies are above minimum operating levels and stable. The reset signal remains active until  $V_{DD}$  rises above the minimum preset voltage level for time period  $t_{PD}$ .

**MANUAL RESET**

The manual-reset input ( $\overline{MR}$ ) allows the user to trigger a reset by using a push-button switch or by electronically driving the input low. The MR input is an active LOW debounced input. Reset is asserted anytime the MR pin is pulled low to less than 100mV for the minimum MR pulse width or longer. The reset output remains asserted low for  $t_{PD}$ , typically 120ms and then is released. Figures 2 and 3 illustrate the CAT885's operation and RST output response times.
