

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Independent Clock HOTLink II™ Dual Serializer and Dual Reclocking Deserializer

Features

- Second-generation HOTLink® technology
- Compliant to SMPTE 292M and SMPTE 259M video standards
- Dual-channel video serializer plus dual channel video reclocking deserializer
 - 195- to 1500-Mbps serial data signaling rate
 - Simultaneous operation at different signaling rates
- Supports reception of either 1.485 or 1.485/1.001 Gbps data rate with the same training clock
- Supports half-rate and full-rate clocking
- Internal phase-locked loops (PLLs) with no external PLL components
- Selectable differential PECL-compatible serial inputs
 - Internal DC-restoration
- Redundant differential PECL-compatible serial outputs
 - No external bias resistors required
 - Signaling-rate controlled edge-rates
 - Internal source termination
- Synchronous LVTTTL parallel interface
- JTAG boundary scan
- Built-In Self-Test (BIST) for at-speed link testing
- Link Quality Indicator
 - Analog signal detect
 - Digital signal detect
- Low-power 2.5 W at 3.3 V typical
- Single 3.3 V supply
- Thermally enhanced BGA
- Pb-free package option available
- 0.25 μ BiCMOS technology

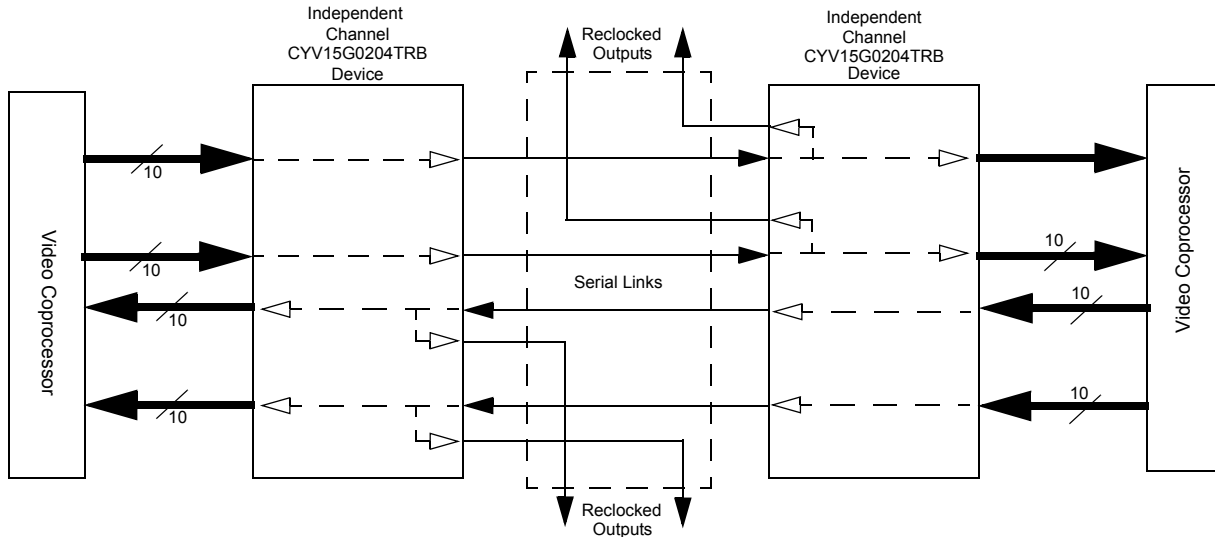

Functional Description

The CYV15G0204TRB Independent Clock HOTLink II™ Dual Serializer and Dual Reclocking Deserializer is a point-to-point or point-to-multipoint communications building block enabling transfer of data over a variety of high-speed serial links including SMPTE 292M and SMPTE 259M video applications. It supports signaling rates in the range of 195 to 1500 Mbps per serial link. All transmit and receive channels are independent and can operate simultaneously at different rates. Each transmit channel accepts 10-bit parallel characters in an Input Register and converts them to serial data. Each receive channel accepts serial data and converts it to 10-bit parallel characters and presents these characters to an Output Register. The received serial data can also be reclocked and retransmitted through the reclocker serial outputs. [Figure 1](#) illustrates typical connections between independent video co-processors and corresponding CYV15G0204TRB chips.

The CYV15G0204TRB satisfies the SMPTE 259M and SMPTE 292M compliance as per SMPTE EG34-1999 Pathological Test Requirements.

As a second-generation HOTLink device, the CYV15G0204TRB extends the HOTLink family with enhanced levels of integration and faster data rates, while maintaining serial-link compatibility (data and BIST) with other HOTLink devices. Each transmit (TX) channel of the CYV15G0204TRB HOTLink II device accepts scrambled 10-bit transmission characters. These characters are serialized and output from dual Positive ECL (PECL) compatible differential transmission-line drivers at a bit-rate of either 10- or 20-times the input reference clock for that channel.

Figure 1. HOTLink II™ System Connections

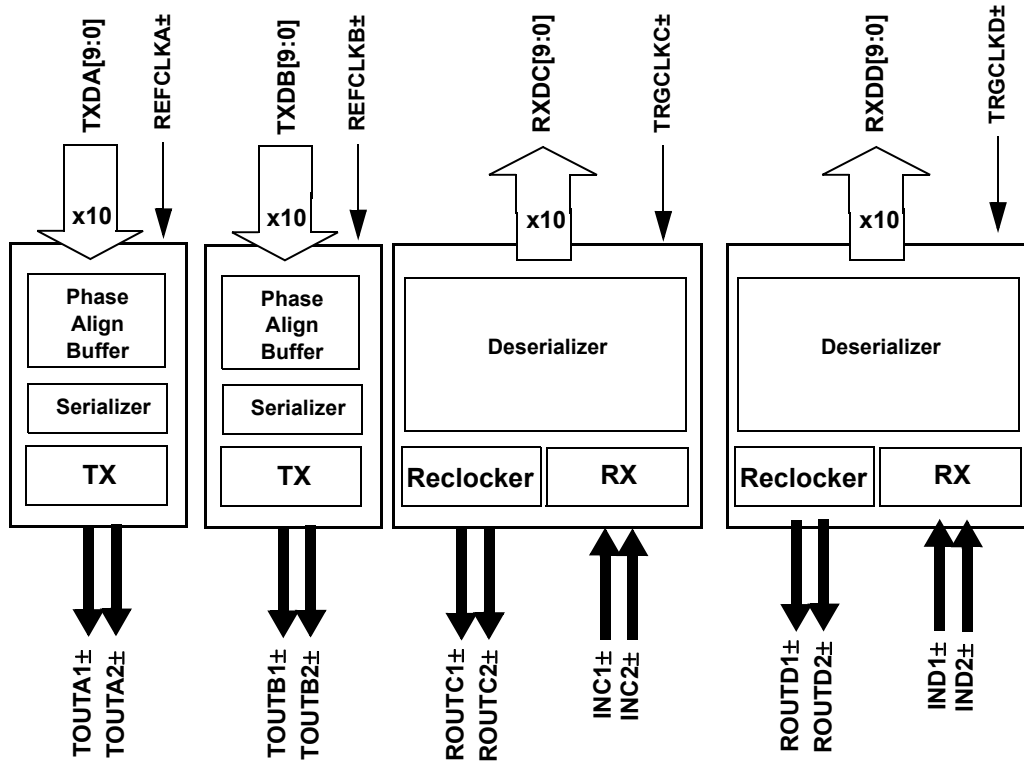

Each receive (RX) channel of the CYV15G0204TRB HOTLink II device accepts a serial bit-stream from one of two selectable PECL-compatible differential line receivers, and using a completely integrated Clock and Data Recovery PLL, recovers the timing information necessary for data reconstruction. The recovered bit-stream is relocked and retransmitted through the reclocker serial outputs. Also, the recovered serial data is deserialized and presented to the destination host system.

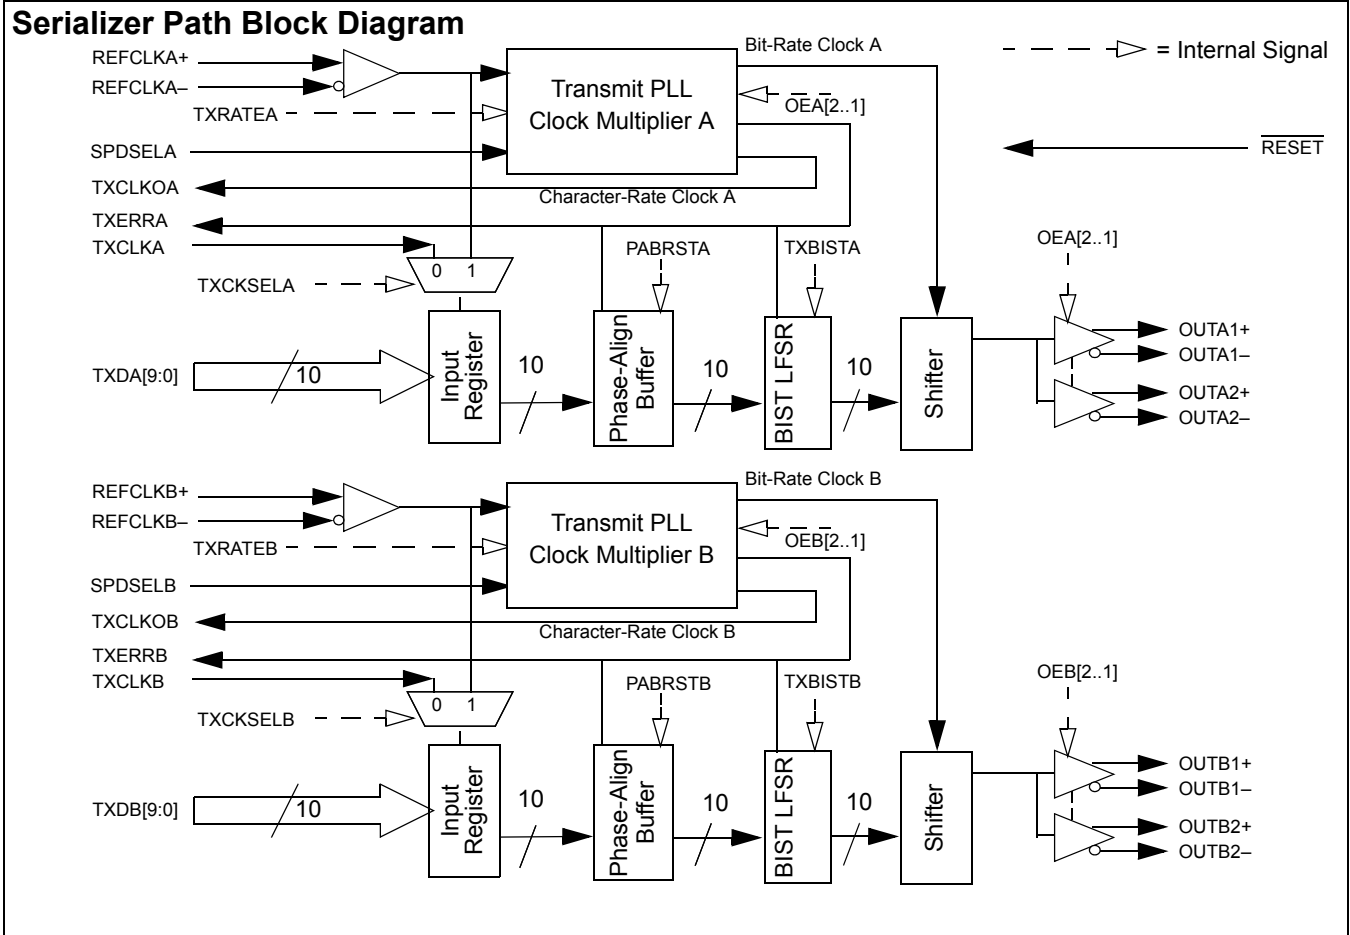

Each transmit and receive channel contains an independent BIST pattern generator and checker, respectively. This BIST

hardware allows at-speed testing of the high-speed serial data paths in each transmit and receive section, and across the inter-connecting links.

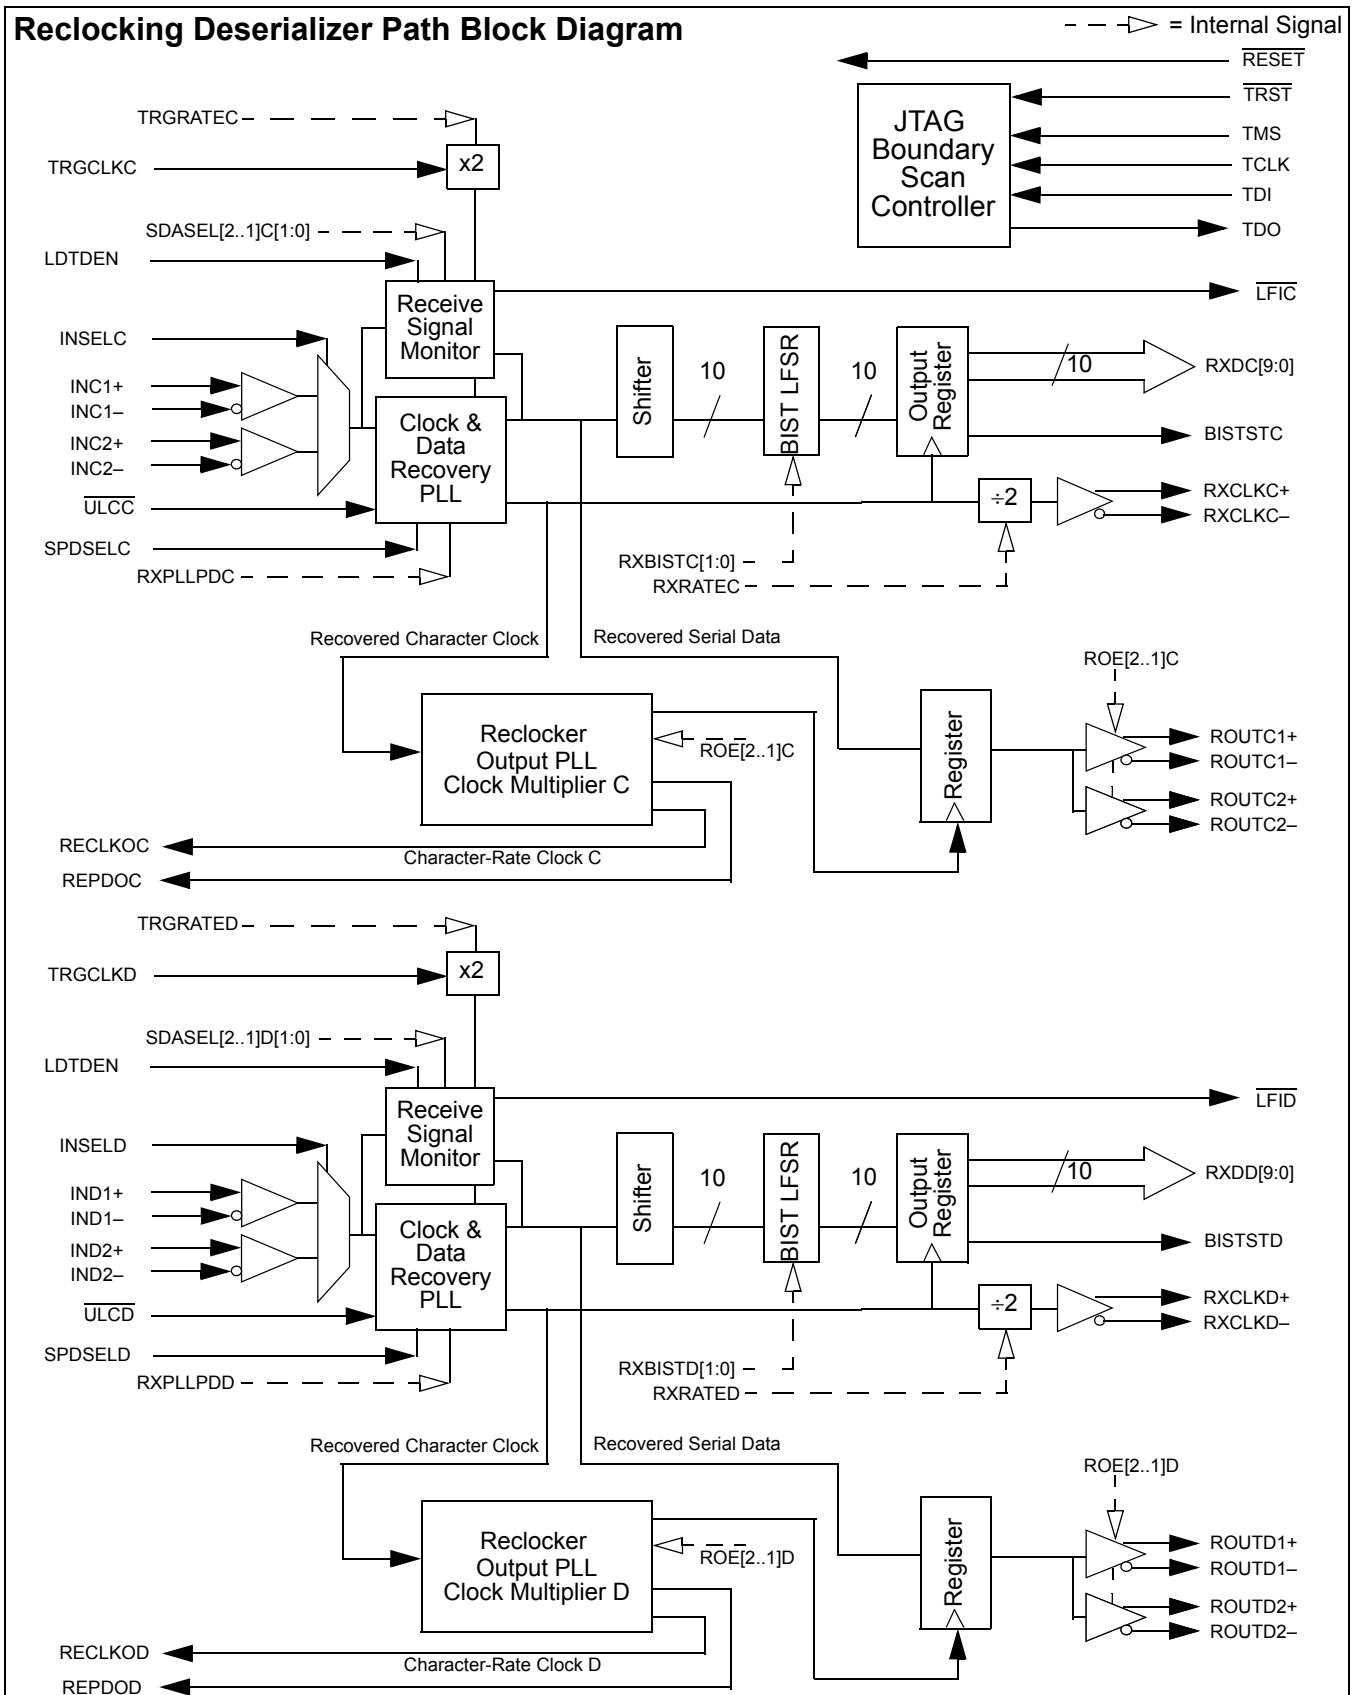

The CYV15G0204TRB is ideal for SMPTE applications where different data rates and serial interface standards are necessary for each channel. Some applications include multi-format routers, switchers, format converters, SDI monitors, cameras, and camera control units.

Pin Definitions

CYV15G0204TRB HOTLink II Dual Serializer and Dual Reclocking Deserializer

Name	I/O Characteristics	Signal Description
Transmit Path Data and Status Signals		
TXDA[7:0] TXDB[7:0]	LVTTL Input, synchronous, sampled by the associated TXCLKx [↑] or REFCLKx [↑] [2]	Transmit Data Inputs. TXDx[9:0] data inputs are captured on the rising edge of the transmit interface clock. The transmit interface clock is selected by the TXCKSELx latch via the device configuration interface.
TXERRA TXERRB	LVTTL Output, synchronous to REFCLKx [↑] [3], asynchronous to transmit channel enable / disable, asynchronous to loss or return of REFCLKx [±]	<p>Transmit Path Error. TXERRx is asserted HIGH to indicate detection of a transmit Phase-Align Buffer underflow or overflow. If an underflow or overflow condition is detected, TXERRx, for the channel in error, is asserted HIGH and remains asserted until the transmit Phase-Align Buffer is re-centered with the PABRSTx latch via the device configuration interface. When TXBISTx = 0, the BIST progress is presented on the associated TXERRx output. The TXERRx signal pulses HIGH for one transmit-character clock period to indicate a pass through the BIST sequence after every 511 character times.</p> <p>TXERRx is also asserted HIGH, when any of the following conditions is true:</p> <ul style="list-style-type: none"> ■ The TXPLL for the associated channel is powered down. This occurs when OE2x and OE1x for a channel are both disabled by setting OE2x = 0 and OE1x = 0. ■ The absence of the REFCLKx[±] signal.
Transmit Path Clock Signals		
REFCLKA [±] REFCLKB [±]	Differential LVPECL or single-ended LVTTL input clock	Reference Clock. REFCLKx [±] clock inputs are used as the timing references for the transmit PLL. These input clocks may also be selected to clock the transmit parallel interface. When driven by a single-ended LVCMOS or LVTTL clock source, connect the clock source to either the true or complement REFCLKx input, and leave the alternate REFCLKx input open (floating). When driven by an LVPECL clock source, the clock must be a differential clock, using both inputs.
TXCLKA TXCLKB	LVTTL Clock Input, internal pull-down	Transmit Path Input Clock. When configuration latch TXCKSELx = 0, the associated TXCLKx input is selected as the character-rate input clock for the TXDx[9:0] input. In this mode, the TXCLKx input must be frequency-coherent to its associated TXCLKOx output clock, but may be offset in phase by any amount. After initialized, TXCLKx is allowed to drift in phase as much as ±180 degrees. If the input phase of TXCLKx drifts beyond the handling capacity of the Phase Align Buffer, TXERRx is asserted to indicate the loss of data, and remains asserted until the Phase Align Buffer is initialized. The phase of the TXCLKx input clock relative to its associated REFCLKx [±] is initialized when the configuration latch PABRSTx is written as 0. When the associated TXERRx is deasserted, the Phase Align Buffer is initialized and input characters are correctly captured.
TXCLKOA TXCLKOB	LVTTL Output	Transmit Clock Output. TXCLKOx output clock is synthesized by each channel's transmit PLL and operates synchronous to the internal transmit character clock. TXCLKOx operates at either the same frequency as REFCLKx [±] (TXRATEx = 0), or at twice the frequency of REFCLKx [±] (TXRATEx = 1). The transmit clock outputs have no fixed phase relationship to REFCLKx [±] .

Notes

2. When REFCLKx[±] is configured for half-rate operation, these inputs are sampled relative to both the rising and falling edges of the associated REFCLKx[±].
3. When REFCLKx[±] is configured for half-rate operation, these outputs are presented relative to both the rising and falling edges of the associated REFCLKx[±].

Pin Definitions (continued)

CYV15G0204TRB HOTLink II Dual Serializer and Dual Reclocking Deserializer

Name	I/O Characteristics	Signal Description
Receive Path Data and Status Signals		
RXDC[9:0] RXDD[9:0]	LVTTL Output, synchronous to the RXCLK± output	Parallel Data Output. RXDx[9:0] parallel data outputs change relative to the receive interface clock. If RXCLKx± is a full-rate clock, the RXCLKx± clock outputs are complementary clocks operating at the character rate. The RXDx[9:0] outputs for the associated receive channels follow rising edge of RXCLKx+ or falling edge of RXCLKx-. If RXCLKx± is a half-rate clock, the RXCLKx± clock outputs are complementary clocks operating at half the character rate. The RXDx[9:0] outputs for the associated receive channels follow both the falling and rising edges of the associated RXCLKx± clock outputs. When BIST is enabled on the receive channel, the BIST status is presented on the RXDx[1:0] and BISTSTx outputs. See Table 6 on page 22 for each status reported by the BIST state machine. Also, while BIST is enabled, the RXDx[9:2] outputs should be ignored.
BISTSTC BISTSTD	LVTTL Output, synchronous to the RXCLKx ± output	BIST Status Output. When RXBISTx[1:0] = 10, BISTSTx (along with RXDx[1:0]) displays the status of the BIST reception. See Table 6 on page 22 for the BIST status reported for each combination of BISTSTx and RXDx[1:0]. When RXBISTx[1:0] ≠ 10, BISTSTx should be ignored.
REPDOC REPDOD	Asynchronous to reclocker output channel enable / disable	Reclocker Powered Down Status Output. REPDOx is asserted HIGH, when the associated channel's reclocker output logic is powered down. This occurs when ROE2x and ROE1x are both disabled by setting ROE2x = 0 and ROE1x = 0.
Receive Path Clock Signals		
TRGCLKC± TRGCLKD±	Differential LVPECL or single-ended LVTTL input clock	CDR PLL Training Clock. TRGCLKx± clock inputs are used as the reference source for the frequency detector (Range Controller) of the associated receive PLL to reduce PLL acquisition time. In the presence of valid serial data, the recovered clock output of the receive CDR PLL (RXCLKx±) has no frequency or phase relationship with TRGCLKx±. When driven by a single-ended LVCMOS or LVTTL clock source, connect the clock source to either the true or complement TRGCLKx input, and leave the alternate TRGCLKx input open (floating). When driven by an LVPECL clock source, the clock must be a differential clock, using both inputs.
RXCLKC± RXCLKD±	LVTTL Output Clock	Receive Clock Output. RXCLKx± is the receive interface clock used to control timing of the RXDx[9:0] parallel outputs. These true and complement clocks are used to control timing of data output transfers. These clocks are output continuously at either the half-character rate (1/20 th the serial bit-rate) or character rate (1/10 th the serial bit-rate) of the data being received, as selected by RXRATEx.
RECLKOC RECLKOD	LVTTL Output	Reclocker Clock Output. RECLKOx output clock is synthesized by the associated reclocker output PLL and operates synchronous to the internal recovered character clock. RECLKOx operates at either the same frequency as RXCLKx± (RXRATEx = 0), or at twice the frequency of RXCLKx± (RXRATEx = 1). The reclocker clock outputs have no fixed phase relationship to RXCLKx±.
Device Control Signals		
RESET	LVTTL Input, asynchronous, internal pull-up	Asynchronous Device Reset. RESET initializes all state machines, counters, and configuration latches in the device to a known state. RESET must be asserted LOW for a minimum pulse width. When the reset is removed, all state machines, counters and configuration latches are at an initial state. As per the JTAG specifications the device RESET cannot reset the JTAG controller. Therefore, the JTAG controller has to be reset separately. See "JTAG Support" on page 22 for the methods to reset the JTAG state machine. See Table 4 on page 18 for the initialize values of the device configuration latches.

Pin Definitions (continued)

CYV15G0204TRB HOTLink II Dual Serializer and Dual Reclocking Deserializer

Name	I/O Characteristics	Signal Description
LDTDEN	LVTTL Input, internal pull-up	Level Detect Transition Density Enable. When LDTDEN is HIGH, the Signal Level Detector, Range Controller, and Transition Density Detector are all enabled to determine if the RXPLL tracks TRGCLKx± or the selected input serial data stream. If the Signal Level Detector, Range Controller, or Transition Density Detector are out of their respective limits while LDTDEN is HIGH, the RXPLL locks to TRGCLKx± until such a time they become valid. The SDASEL[A..D][1:0] inputs are used to configure the trip level of the Signal Level Detector. The Transition Density Detector limit is one transition in every 60 consecutive bits. When LDTDEN is LOW, only the Range Controller is used to determine if the RXPLL tracks TRGCLKx± or the selected input serial data stream. It is recommended to set LDTDEN = HIGH.
<u>ULCC</u> ULCD	LVTTL Input, internal pull-up	Use Local Clock. When <u>ULC</u> x is LOW, the RXPLL is forced to lock to <u>TRGCLK</u> x± instead of the received serial data stream. While <u>ULC</u> x is LOW, the LFIx for the associated channel is LOW indicating a link fault. When <u>ULC</u> x is HIGH, the RXPLL performs Clock and Data Recovery functions on the input data streams. This function is used in applications in which a stable RXCLKx± is needed. In cases when there is an absence of valid data transitions for a long period of time, or the high-gain differential serial inputs (INx±) are left floating, there may be brief frequency excursions of the RXCLKx± outputs from TRGCLKx±.
SPDSELA SPDSELB SPDSELC SPDSELD	3-Level Select ^[4] static control input	Serial Rate Select. The SPDSELx inputs specify the operating signaling-rate range of each channel's transmit (channels A and B) or receive PLL (channels C and D). LOW = 195 – 400 MBd MID = 400 – 800 MBd HIGH = 800 – 1500 MBd.
INSEL INSELD	LVTTL Input, asynchronous	Receive Input Selector. The INSELx input determines which external serial bit stream is passed to the receiver's Clock and Data Recovery circuit. When INSELx is HIGH, the Primary Differential Serial Data Input, INx1±, is selected for the associated receive channel. When INSELx is LOW, the Secondary Differential Serial Data Input, INx2±, is selected for the associated receive channel.
<u>LFIC</u> LFID	LVTTL Output, asynchronous	Link Fault Indication Output. LFIx is an output status indicator signal. LFIx is the logical OR of six internal conditions. LFIx is asserted LOW when any of the following conditions is true: <ul style="list-style-type: none"> ■ Received serial data rate outside expected range ■ Analog amplitude below expected levels ■ Transition density lower than expected ■ Receive channel disabled ■ <u>ULC</u>x is LOW ■ Absence of TRGCLKx±.

Notes

4. 3-Level Select inputs are used for static configuration. These are ternary inputs that make use of logic levels of LOW, MID, and HIGH. The LOW level is usually implemented by direct connection to V_{SS} (ground). The HIGH level is usually implemented by direct connection to V_{CC} (power). The MID level is usually implemented by not connecting the input (left floating), which allows it to self bias to the proper level.

Pin Definitions (continued)

CYV15G0204TRB HOTLink II Dual Serializer and Dual Reclocking Deserializer

Name	I/O Characteristics	Signal Description
Device Configuration and Control Bus Signals		
WREN	LVTTL input, asynchronous, internal pull-up	Control Write Enable. The WREN input writes the values of the DATA[6:0] bus into the latch specified by the address location on the ADDR[3:0] bus. ^[5]
ADDR[3:0]	LVTTL input asynchronous, internal pull-up	Control Addressing Bus. The ADDR[3:0] bus is the input address bus used to configure the device. The WREN input writes the values of the DATA[6:0] bus into the latch specified by the address location on the ADDR[3:0] bus. ^[5] Table 4 on page 18 lists the configuration latches within the device, and the initialization value of the latches upon the assertion of RESET. Table 5 on page 21 shows how the latches are mapped in the device.
DATA[6:0]	LVTTL input asynchronous, internal pull-up	Control Data Bus. The DATA[6:0] bus is the input data bus used to configure the device. PABRSTB[A..B]	Internal Latch ^[6]	Transmit Clock Phase Alignment Buffer Reset.
Factory Test Modes		
SCANEN2	LVTTL input, internal pull-down	Factory Test 2. SCANEN2 input is for factory testing only. This input may be left as a NO CONNECT, or GND only.
TMEN3	LVTTL input, internal pull-down	Factory Test 3. TMEN3 input is for factory testing only. This input may be left as a NO CONNECT, or GND only.

Notes

- See [Device Configuration and Control Interface](#) for detailed information on the operation of the Configuration Interface.
- See [Device Configuration and Control Interface](#) for detailed information on the internal latches.

Pin Definitions (continued)

CYV15G0204TRB HOTLink II Dual Serializer and Dual Reclocking Deserializer

Name	I/O Characteristics	Signal Description
Analog I/O		
TOUTA1± TOUTB1±	CML Differential Output	Transmitter Primary Differential Serial Data Output. The transmitter TOUTx1± PECL-compatible CML outputs (+3.3 V referenced) are capable of driving terminated transmission lines or standard fiber-optic transmitter modules, and must be AC-coupled for PECL-compatible connections.
TOUTA2± TOUTB2±	CML Differential Output	Transmitter Secondary Differential Serial Data Output. The transmitter TOUTx2± PECL-compatible CML outputs (+3.3 V referenced) are capable of driving terminated transmission lines or standard fiber-optic transmitter modules, and must be AC-coupled for PECL-compatible connections.
ROUTC1± ROUDD1±	CML Differential Output	Reclocker Primary Differential Serial Data Output. The reclocker ROUTx1± PECL-compatible CML outputs (+3.3 V referenced) are capable of driving terminated transmission lines or standard fiber-optic transmitter modules, and must be AC-coupled for PECL-compatible connections.
ROUTC2± ROUDD2±	CML Differential Output	Reclocker Secondary Differential Serial Data Output. The reclocker ROUTx2± PECL-compatible CML outputs (+3.3 V referenced) are capable of driving terminated transmission lines or standard fiber-optic transmitter modules, and must be AC-coupled for PECL-compatible connections.
INC1± IND1±	Differential Input	Primary Differential Serial Data Input. The INx1± input accepts the serial data stream for deserialization. The INx1± serial stream is passed to the receive CDR circuit to extract the data content when INSELx = HIGH.
INC2± IND2±	Differential Input	Secondary Differential Serial Data Input. The INx2± input accepts the serial data stream for deserialization. The INx2± serial stream is passed to the receiver CDR circuit to extract the data content when INSELx = LOW.
JTAG Interface		
TMS	LVTTL Input, internal pull-up	Test Mode Select. Used to control access to the JTAG Test Modes. If maintained high for ≥5 TCLK cycles, the JTAG test controller is reset.
TCLK	LVTTL Input, internal pull-down	JTAG Test Clock.
TDO	3-State LVTTL Output	Test Data Out. JTAG data output buffer. High-Z while JTAG test mode is not selected.
TDI	LVTTL Input, internal pull-up	Test Data In. JTAG data input port.
TRST	LVTTL Input, internal pull-up	JTAG reset signal. When asserted (LOW), this input asynchronously resets the JTAG test access port controller.
Power		
V _{CC}		+3.3 V Power.
GND		Signal and Power Ground for all internal circuits.

CYV15G0204TRB HOTLink II Operation

The CYV15G0204TRB is a highly configurable, independent clocking, device designed to support reliable transfer of large quantities of digital video data, using high-speed serial links from multiple sources to multiple destinations.

CYV15G0204TRB Transmit Data Path

Input Register

The parallel input bus TXDx[9:0] can be clocked in using TXCLKx (TXCKSELx = 0) or REFCLKx (TXCKSELx = 1).

Phase-Align Buffer

Data from each Input Register is passed to the associated Phase-Align Buffer, when the TXDx[9:0] input registers are clocked using TXCLKx (TXCKSELx = 0 and TXRATEx = 0). When the TXDx[9:0] input registers are clocked using REFCLKx± (TXCKSELx = 1) and REFCLKx± is a full-rate clock, the associated Phase Alignment Buffer in the transmit path is bypassed. These buffers are used to absorb clock phase differences between the TXCLKx input clock and the internal character clock for that channel.

After initialized, TXCLKx is allowed to drift in phase as much as ±180 degrees. If the input phase of TXCLKx drifts beyond the handling capacity of the Phase Align Buffer, TXERRx is asserted to indicate the loss of data, and remains asserted until the Phase Align Buffer is initialized. The phase of the TXCLKx relative to its associated internal character rate clock is initialized when the configuration latch PABRSTx is written as 0. When the associated TXERRx is deasserted, the Phase Align Buffer is initialized and input characters are correctly captured.

If the phase offset, between the initialized location of the input clock and REFCLKx, exceeds the skew handling capabilities of the Phase-Align Buffer, an error is reported on that channel's TXERRx output. This output indicates an error continuously until the Phase-Align Buffer for that channel is reset. While the error remains active, the transmitter for that channel outputs a continuous "1001111000" character to indicate to the remote receiver that an error condition is present in the link.

Transmit BIST

Each transmit channel contains an internal pattern generator that can be used to validate both the link and device operation. These generators are enabled by the associated TXBISTx latch via the device configuration interface. When enabled, a register in the associated transmit channel becomes a signature pattern generator by logically converting to a Linear Feedback Shift Register (LFSR). This LFSR generates a 511-character sequence. This provides a predictable yet pseudo-random sequence that can be matched to an identical LFSR in the attached Receiver(s).

A device reset (RESET sampled LOW) presets the BIST Enable Latches to disable BIST on both channels.

All data present at the associated TXDx[9:0] inputs are ignored when BIST is active on that channel.

Notes

- 3-Level Select inputs are used for static configuration. These are ternary inputs that make use of logic levels of LOW, MID, and HIGH. The LOW level is usually implemented by direct connection to V_{SS} (ground). The HIGH level is usually implemented by direct connection to V_{CC} (power). The MID level is usually implemented by not connecting the input (left floating), which allows it to self bias to the proper level.

Transmit PLL Clock Multiplier

Each Transmit PLL Clock Multiplier accepts a character-rate or half-character-rate external clock at the associated REFCLKx± input, and that clock is multiplied by 10 or 20 (as selected by TXRATEx) to generate a bit-rate clock for use by the transmit shifter. It also provides a character-rate clock used by the transmit paths, and outputs this character rate clock as TXCLKOx.

Each clock multiplier PLL can accept a REFCLKx± input between 19.5 MHz and 150 MHz, however, this clock range is limited by the operating mode of the CYV15G0204TRB clock multiplier (TXRATEx) and by the level on the associated SPDSELx input.

SPDSELx are 3-level select^[7] inputs that select one of three operating ranges for the serial data outputs and inputs of the associated channel. The operating serial signaling-rate and allowable range of REFCLKx± frequencies are listed in Table 1.

Table 1. Operating Speed Settings

SPDSELx	TXRATEx	REFCLKx± Frequency (MHz)	Signaling Rate (Mbps)
LOW	1	reserved	195–400
	0	19.5–40	
MID (Open)	1	20–40	400–800
	0	40–80	
HIGH	1	40–75	800–1500
	0	80–150	

The REFCLKx± inputs are differential inputs with each input internally biased to 1.4 V. If the REFCLKx+ input is connected to a TTL, LVTTTL, or LVCMOS clock source, the input signal is recognized when it passes through the internally biased reference point. When driven by a single-ended TTL, LVTTTL, or LVCMOS clock source, connect the clock source to either the true or complement REFCLKx input, and leave the alternate REFCLKx input open (floating).

When both the REFCLKx+ and REFCLKx– inputs are connected, the clock source must be a differential clock. This can either be a differential LVPECL clock that is DC-or AC-coupled or a differential LVTTTL or LVCMOS clock.

By connecting the REFCLKx– input to an external voltage source, it is possible to adjust the reference point of the REFCLKx+ input for alternate logic levels. When doing so, it is necessary to ensure that the input differential crossing point remains within the parametric range supported by the input.

Transmit Serial Output Drivers

The serial output interface drivers use differential Current Mode Logic (CML) drivers to provide source-matched drivers for 50Ω transmission lines. These drivers accept data from the Transmit Shifters. These drivers have signal swings equivalent to that of standard PECL drivers, and are capable of driving AC-coupled optical modules or transmission lines.

Transmit Channels Enabled

Each driver can be enabled or disabled separately via the device configuration interface.

When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. A device reset (RESET sampled LOW) disables all output drivers.

Note. When a disabled transmit channel (that is, both outputs disabled) is re-enabled:

- data on the serial outputs may not meet all timing specifications for up to 250 μ s
- the state of the phase-align buffer cannot be guaranteed, and a phase-align reset is required if the phase-align buffer is used

CYV15G0204TRB Receive Data Path

Serial Line Receivers

Two differential Line Receivers, INx1 \pm and INx2 \pm , are available on each channel for accepting serial data streams. The active Serial Line Receiver on a channel is selected using the associated INSELx input. The Serial Line Receiver inputs are differential, and can accommodate wire interconnect and filtering losses or transmission line attenuation greater than 16 dB. For normal operation, these inputs should receive a signal of at least $V_{DIFF} > 100$ mV, or 200 mV peak-to-peak differential. Each Line Receiver can be DC- or AC-coupled to +3.3 V powered fiber-optic interface modules (any ECL/PECL family, not limited to 100K PECL) or AC-coupled to +5 V powered optical modules. The common-mode tolerance of these line receivers accommodates a wide range of signal termination voltages. Each receiver provides internal DC-restoration, to the center of the receiver's common mode range, for AC-coupled signals.

Signal Detect/Link Fault

Each selected Line Receiver (that is, that routed to the clock and data recovery PLL) is simultaneously monitored for

- analog amplitude above amplitude level selected by SDASELx
- transition density above the specified limit
- range controls report the received data stream inside normal frequency range (± 1500 ppm^[9])
- receive channel enabled
- Presence of reference clock
- \overline{ULCx} is not asserted.

All of these conditions must be valid for the Signal Detect block to indicate a valid signal is present. This status is presented on the LFix (Link Fault Indicator) output associated with each receive channel, which changes synchronous to the receive interface clock.

Notes

8. The peak amplitudes listed in this table are for typical waveforms that have generally 3–4 transitions for every ten bits. In a worse case environment the signals may have a sine-wave appearance (highest transition density with repeating 0101...). Signal peak amplitudes levels within this environment type could increase the values in the table above by approximately 100 mV.
9. TRGCLKx \pm has no phase or frequency relationship with the recovered clock(s) and only acts as a centering reference to reduce clock synchronization time. TRGCLKx \pm must be within ± 1500 PPM ($\pm 0.15\%$) of the transmitter PLL reference (REFCLKx \pm) frequency. Although transmitting to a HOTLink II receiver channel necessitates the frequency difference between the transmitter and receiver reference clocks to be within ± 1500 -PPM, the stability of the crystal needs to be within the limits specified by the appropriate standard when transmitting to a remote receiver that is compliant to that standard.

Analog Amplitude

While most signal monitors are based on fixed constants, the analog amplitude level detection is adjustable to allow operation with highly attenuated signals, or in high-noise environments. The analog amplitude level detection is set by the SDASELx latch via device configuration interface. The SDASELx latch sets the trip point for the detection of a valid signal at one of three levels, as listed in Table 2. This control input affects the analog monitors for both receive channels. The Analog Signal Detect monitors are active for the Line Receiver as selected by the associated INSELx input.

Table 2. Analog Amplitude Detect Valid Signal Levels^[8]

SDASEL	Typical Signal with Peak Amplitudes Above
00	Analog Signal Detector is disabled
01	140 mV p-p differential
10	280 mV p-p differential
11	420 mV p-p differential

Transition Density

The Transition Detection logic checks for the absence of transitions spanning greater than six transmission characters (60 bits). If no transitions are present in the data received, the Detection logic for that channel asserts LFix.

Range Controls

The CDR circuit includes logic to monitor the frequency of the PLL Voltage Controlled Oscillator (VCO) used to sample the incoming data stream. This logic ensures that the VCO operates at, or near the rate of the incoming data stream for two primary cases:

- when the incoming data stream resumes after a time in which it has been “missing.”
- when the incoming data stream is outside the acceptable signaling rate range.

To perform this function, the frequency of the RXPLL VCO is periodically compared to the frequency of the TRGCLKx \pm input. If the VCO is running at a frequency beyond ± 1500 ppm^[9] as defined by the TRGCLKx \pm frequency, it is periodically forced to the correct frequency (as defined by TRGCLKx \pm , SPDSELx, and TRGRATEx) and then released in an attempt to lock to the input data stream.

The sampling and relock period of the Range Control is calculated as follows: RANGE_CONTROL_SAMPLING_PERIOD = (RECOVERED BYTE CLOCK PERIOD) * (4096).

During the time that the Range Control forces the RXPLL VCO to track TRGCLKx \pm , the LFix output is asserted LOW. After a valid serial data stream is applied, it may take up to one RANGE CONTROL SAMPLING PERIOD before the PLL locks to the input data stream, after which LFix should be HIGH.

The operating serial signaling-rate and allowable range of TRGCLK \pm frequencies are listed in Table 3.

Table 3. Operating Speed Settings

SPDSELx	TRGRATEx	TRGCLKx± Frequency (MHz)	Signaling Rate (Mbps)
LOW	1	reserved	195 – 400
	0	19.5–40	
MID (Open)	1	20–40	400–800
	0	40–80	
HIGH	1	40–75	800–1500
	0	80–150	

Receive Channel Enabled

The CYV15G0204TRB contains two receive channels that can be independently enabled and disabled. Each channel can be enabled or disabled separately through the RXPLLDPx input latch as controlled by the device configuration interface. When the RXPLLDPx latch = 0, the associated PLL and analog circuitry of the channel is disabled. Any disabled channel indicates a constant link fault condition on the LFix output. When RXPLLDPx = 1, the associated PLL and receive channel is enabled to receive a serial stream.

When a disabled receive channel is reenabled, the status of the associated LFix output and data on the parallel outputs for the associated channel may be indeterminate for up to 2 ms.

Clock/Data Recovery

The extraction of a bit-rate clock and recovery of bits from each received serial stream is performed by a separate CDR block within each receive channel. The clock extraction function is performed by an integrated PLL that tracks the frequency of the transitions in the incoming bit stream and align the phase of the internal bit-rate clock to the transitions in the selected serial data stream.

Each CDR accepts a character-rate (bit-rate ÷ 10) or half-character-rate (bit-rate ÷ 20) training clock from the associated TRGCLKx± input. This TRGCLKx± input is used to

- ensure that the VCO (within the CDR) is operating at the correct frequency (rather than a harmonic of the bit-rate)
- reduce PLL acquisition time
- limit unlocked frequency excursions of the CDR VCO when there is no input data present at the selected Serial Line Receiver.

Regardless of the type of signal present, the CDR attempts to recover a data stream from it. If the signalling rate of the recovered data stream is outside the limits set by the range control monitors, the CDR tracks TRGCLKx± instead of the data stream. After the CDR output (RXCLK±) frequency returns back close to TRGCLKx± frequency, the CDR input is switched back to the input data stream. If no data is present at the selected line receiver, this switching behavior may result in brief RXCLK± frequency excursions from TRGCLKx±. However, the validity of the input data stream is indicated by the LFix output. The

Note

10. TRGCLKx± has no phase or frequency relationship with the recovered clock(s) and only acts as a centering reference to reduce clock synchronization time. TRGCLKx± must be within ±1500 PPM (±0.15%) of the transmitter PLL reference (REFCLKx±) frequency. Although transmitting to a HOTLink II receiver channel necessitates the frequency difference between the transmitter and receiver reference clocks to be within ±1500-PPM, the stability of the crystal needs to be within the limits specified by the appropriate standard when transmitting to a remote receiver that is compliant to that standard.

frequency of TRGCLKx± is required to be within ±1500 ppm^[10] of the frequency of the clock that drives the REFCLKx± input of the remote transmitter to ensure a lock to the incoming data stream. This large ppm tolerance allows the CDR PLL to reliably receive a 1.485 or 1.485/1.001 Gbps SMPTE HD-SDI data stream with a constant TRGCLK frequency.

For systems using multiple or redundant connections, the LFix output can be used to select an alternate data stream. When an LFix indication is detected, external logic can toggle selection of the associated INx1± and INx2± input through the associated INSELx input. When a port switch takes place, it is necessary for the receive PLL for that channel to reacquire the new serial stream.

Reclocker

Each receive channel performs a reclocker function on the incoming serial data. To do this, the Clock and Data Recovery PLL first recovers the clock from the data. The data is retimed by the recovered clock and then passed to an output register. Also, the recovered character clock from the receive PLL is passed to the reclocker output PLL which generates the bit clock that is used to clock the retimed data into the output register. This data stream is then transmitted through the differential serial outputs.

Reclocker Serial Output Drivers

The serial output interface drivers use differential Current Mode Logic (CML) drivers to provide source-matched drivers for 50Ω transmission lines. These drivers accept data from the reclocker output register in the reclocker channel. These drivers have signal swings equivalent to that of standard PECL drivers, and are capable of driving AC-coupled optical modules or transmission lines.

Reclocker Output Channels Enabled

Each driver can be enabled or disabled separately via the device configuration interface.

When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both reclocker serial drivers for a channel are in this disabled state, the associated internal reclocker logic is also powered down. The deserialization logic and parallel outputs remain enabled. A device reset (RESET sampled LOW) disables all output drivers.

Note. When the disabled reclocker function (that is, both outputs disabled) is re-enabled, the data on the reclocker serial outputs may not meet all timing specifications for up to 250 μs.

Output Bus

The receive channel presents a 10-bit data signal (and a BIST status signal when RXBISTx[1:0] = 10).

Receive BIST Operation

Each receiver channel contains an internal pattern checker that can be used to validate both device and link operation. These pattern checkers are enabled by the associated RXBISTx[1:0] latch via the device configuration interface. When enabled, a register in the associated receive channel becomes a signature

pattern generator and checker by logically converting to a Linear Feedback Shift Register (LFSR). This LFSR generates a 511-character sequence. This provides a predictable yet pseudo-random sequence that can be matched to an identical LFSR in the attached Transmitter(s). When synchronized with the received data stream, the associated Receiver checks each character from the deserializer with each character generated by the LFSR and indicates compare errors and BIST status at the RXDx[1:0] and BISTSTx bits of the Output Register.

The BIST status bus {BISTSTx, RXDx[0], RXDx[1]} indicates 010b or 100b for one character period per BIST loop to indicate loop completion. This status can be used to check test pattern progress.

If the number of invalid characters received ever exceeds the number of valid characters by 16, the receive BIST state machine aborts the compare operations and resets the LFSR to look for the start of the BIST sequence again.

A device reset ($\overline{\text{RESET}}$ sampled LOW) presets the BIST Enable Latches to disable BIST on both channels.

BIST Status State Machine

When a receive path is enabled to look for and compare the received data stream with the BIST pattern, the {BISTSTx, RXDx[0], RXDx[1]} bits identify the present state of the BIST compare operation.

The BIST state machine has multiple states, as shown in Figure 2 on page 23 and Table 6 on page 22. When the receive PLL detects an out-of-lock condition, the BIST state is forced to the Start-of-BIST state, regardless of the present state of the BIST state machine. If the number of detected errors ever exceeds the number of valid matches by greater than 16, the state machine is forced to the WAIT_FOR_BIST state where it monitors the receive path for the first character of the next BIST sequence.

Power Control

The CYV15G0204TRB supports user control of the powered up or down state of each transmit and receive channel. The receive channels are controlled by the RXPLLPDx latch via the device configuration interface. When RXPLLPDx = 0, the associated PLL and analog circuitry of the channel is disabled. The transmit channels are controlled by the TOE1x and the TOE2x latches via the device configuration interface. The reclocker function is controlled by the ROE1x and the ROE2x latches via the device configuration interface. When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. When the reclocker serial drivers are disabled,

the reclocker function is disabled, but the deserialization logic and parallel outputs remain enabled.

Device Reset State

When the CYV15G0204TRB is reset by assertion of $\overline{\text{RESET}}$, all state machines, counters, and configuration latches in the device are initialized to a reset state. Additionally, the JTAG controller must also be reset for valid operation (even if JTAG testing is not performed). See "JTAG Support" on page 22 for JTAG state machine initialization. See Table 4 on page 18 for the initialize values of the configuration latches.

Following a device reset, it is necessary to enable the receive channels used for normal operation. This can be done by sequencing the appropriate values on the device configuration interface.^[11]

Device Configuration and Control Interface

The CYV15G0204TRB is highly configurable via the configuration interface. The configuration interface allows each channel to be configured independently. Table 4 on page 18 lists the configuration latches within the device including the initialization value of the latches upon the assertion of $\overline{\text{RESET}}$. Table 5 on page 21 shows how the latches are mapped in the device. Each row in the Table 5 maps to a 7-bit latch bank. There are 12 such write-only latch banks. When WREN = 0, the logic value in the DATA[7:0] is latched to the latch bank specified by the values in ADDR[3:0]. The second column of Table 5 specifies the channels associated with the corresponding latch bank. For example, the first three latch banks (0, 1 and 2) consist of configuration bits for channel A.

Latch Types

There are two types of latch banks: static (S) and dynamic (D). Each channel is configured by 2 static and 1 dynamic latch banks. The S type contain those settings that normally do not change for an application, whereas the D type controls the settings that could change during the application's lifetime. The first and second rows of each channel (address numbers 0, 1, 3, 4, 6, 7, 9, and 10) are the static control latches. The third row of latches for each channel (address numbers 2, 5, 8, and 11) are the dynamic control latches that are associated with enabling dynamic functions within the device.

Static Latch Values

There are some latches in the table that have a static value (that is, 1, 0, or X). The latches that have a '1' or '0' must be configured with their corresponding value each time that their associated latch bank is configured. The latches that have an 'X' are don't cares and can be configured with any value.

Table 4. Device Configuration and Control Latch Descriptions

Name	Signal Description
TXCKSELA TXCKSELB	Transmit Clock Select. The initialization value of the TXCKSELx latch = 1. TXCKSELx selects the clock source used to write data into the Transmit Input Register. When TXCKSELx = 1, the associated input register TXDx[9:0] is clocked by REFCLKx \uparrow . In this mode, the phase alignment buffer in the transmit path is bypassed. When TXCKSELx = 0, the associated TXCLKx \uparrow is used to clock in the input register TXDx[9:0].

Note
11. See *Device Configuration and Control Interface* for detailed information on the operation of the Configuration Interface.

Table 4. Device Configuration and Control Latch Descriptions (continued)

Name	Signal Description
TXRATEA TXRATEB	Transmit PLL Clock Rate Select. The initialization value of the TXRATE _x latch = 0. TXRATE _x is used to select the clock multiplier for the Transmit PLL. When TXRATE _x = 0, each transmit PLL multiplies the associated REFCLK _{x±} input by 10 to generate the serial bit-rate clock. When TXRATE _x = 0, the TXCLKO _x output clocks are full-rate clocks and follow the frequency and duty cycle of the associated REFCLK _{x±} input. When TXRATE _x = 1, each Transmit PLL multiplies the associated REFCLK _{x±} input by 20 to generate the serial bit-rate clock. When TXRATE _x = 1, the TXCLKO _x output clocks are twice the frequency rate of the REFCLK _{x±} input. When TXCLKSEL _x = 1 and TXRATE _x = 1, the Transmit Data Inputs are captured using both the rising and falling edges of REFCLK _x . TXRATE _x = 1 and SPDSEL _x = LOW, is an invalid state and this combination is reserved.
TXBISTA TXBISTB	Transmit Bist Disabled. The initialization value of the TXBIST _x latch = 1. TXBIST _x selects if the transmit BIST is disabled or enabled. When TXBIST _x = 1, the transmit BIST function is disabled. When TXBIST _x = 0, the transmit BIST function is enabled.
TOE2A TOE2B	Secondary Differential Serial Data Output Driver Enable. The initialization value of the TOE2 _x latch = 0. TOE2 _x selects if the TOUT _{x2±} secondary differential output drivers are enabled or disabled. When TOE2 _x = 1, the associated serial data output driver is enabled allowing data to be transmitted from the transmit shifter. When TOE2 _x = 0, the associated serial data output driver is disabled. When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. A device reset (RESET sampled LOW) disables all output drivers.
TOE1A TOE1B	Primary Differential Serial Data Output Driver Enable. The initialization value of the TOE1 _x latch = 0. TOE1 _x selects if the TOUT _{x1±} primary differential output drivers are enabled or disabled. When TOE1 _x = 1, the associated serial data output driver is enabled allowing data to be transmitted from the transmit shifter. When TOE1 _x = 0, the associated serial data output driver is disabled. When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. A device reset (RESET sampled LOW) disables all output drivers.
PABRSTA PABRSTB	Transmit Clock Phase Alignment Buffer Reset. The initialization value of the PABRST _x latch = 1. The PABRST _x is used to re-center the Transmit Phase Align Buffer. When the configuration latch PABRST _x is written as a 0, the phase of the TXCLK _x input clock relative to its associated REFCLK _{x±} is initialized. PABRST is an asynchronous input, but is sampled by each TXCLK _{x↑} to synchronize it to the internal clock domain. PABRST _x is a self clearing latch. This eliminates the requirement of writing a 1 to complete the initialization of the Phase Alignment Buffer.
RXRATEC RXRATED	Receive Clock Rate Select. The initialization value of the RXRATE _x latch = 1. RXRATE _x is used to select the rate of the RXCLK _{x±} clock output. When RXRATE _x = 1, the RXCLK _{x±} clock outputs are complementary clocks that follow the recovered clock operating at half the character rate. Data for the associated receive channels should be latched alternately on the rising edge of RXCLK _{x+} and RXCLK _{x-} . When RXRATE _x = 0, the RXCLK _{x±} clock outputs are complementary clocks that follow the recovered clock operating at the character rate. Data for the associated receive channels should be latched on the rising edge of RXCLK _{x+} or falling edge of RXCLK _{x-} .
SDASEL1C[1:0] SDASEL1D[1:0]	Primary Serial Data Input Signal Detector Amplitude Select. The initialization value of the SDASEL1 _x [1:0] latch = 10. SDASEL1 _x [1:0] selects the trip point for the detection of a valid signal for the IN _{x1±} Primary Differential Serial Data Inputs. When SDASEL1 _x [1:0] = 00, the Analog Signal Detector is disabled. When SDASEL1 _x [1:0] = 01, the typical p-p differential voltage threshold level is 140 mV. When SDASEL1 _x [1:0] = 10, the typical p-p differential voltage threshold level is 280 mV. When SDASEL1 _x [1:0] = 11, the typical p-p differential voltage threshold level is 420 mV.
SDASEL2C[1:0] SDASEL2D[1:0]	Secondary Serial Data Input Signal Detector Amplitude Select. The initialization value of the SDASEL2 _x [1:0] latch = 10. SDASEL2 _x [1:0] selects the trip point for the detection of a valid signal for the IN _{x2±} Secondary Differential Serial Data Inputs. When SDASEL2 _x [1:0] = 00, the Analog Signal Detector is disabled When SDASEL2 _x [1:0] = 01, the typical p-p differential voltage threshold level is 140 mV. When SDASEL2 _x [1:0] = 10, the typical p-p differential voltage threshold level is 280 mV. When SDASEL2 _x [1:0] = 11, the typical p-p differential voltage threshold level is 420 mV.

Table 4. Device Configuration and Control Latch Descriptions (continued)

Name	Signal Description
TRGRATEC TRGRATED	Training Clock Rate Select. The initialization value of the TRGRATE _x latch = 0. TRGRATE _x is used to select the clock multiplier for the training clock input to the associated CDR PLL. When TRGRATE _x = 0, the TRGCLK _{x±} input is not multiplied before it is passed to the CDR PLL. When TRGRATE _x = 1, the TRGCLK _{x±} input is multiplied by 2 before it is passed to the CDR PLL. TRGRATE _x = 1 and SPDSEL _x = LOW is an invalid state and this combination is reserved.
RXPLLPDC RXPLLPDD	Receive Channel Enable. The initialization value of the RXPLLPD _x latch = 0. RXPLLPD _x selects if the associated receive channel is enabled or powered-down. When RXPLLPD _x = 0, the associated receive PLL and analog circuitry are powered-down. When RXPLLPD _x = 1, the associated receive PLL and analog circuitry are enabled.
RXBISTC[1:0] RXBISTD[1:0]	Receive Bist Disable / SMPTE Receive Enable. The initialization value of the RXBIST _x [1:0] latch = 11. For SMPTE data reception, RXBIST _x [1:0] should not remain in this initialization state (11). RXBIST _x [1:0] selects if receive BIST is disabled or enabled and sets the associated channel for SMPTE data reception. When RXBIST _x [1:0] = 01, the receiver BIST function is disabled and the associated channel is set to receive SMPTE data. When RXBIST _x [1:0] = 10, the receive BIST function is enabled and the associated channel is set to receive BIST data. RXBIST _x [1:0] = 00 and RXBIST _x [1:0] = 11 are invalid states.
ROE2C ROE2D	Reclocker Secondary Differential Serial Data Output Driver Enable. The initialization value of the ROE2 _x latch = 0. ROE2 _x selects if the ROUT _{x2±} secondary differential output drivers are enabled or disabled. When ROE2 _x = 1, the associated serial data output driver is enabled allowing data to be transmitted from the transmit shifter. When ROE2 _x = 0, the associated serial data output driver is disabled. When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. A device reset (RESET sampled LOW) disables all output drivers.
ROE1C ROE1D	Reclocker Primary Differential Serial Data Output Driver Enable. The initialization value of the ROE1 _x latch = 0. ROE1 _x selects if the ROUT _{x1±} primary differential output drivers are enabled or disabled. When ROE1 _x = 1, the associated serial data output driver is enabled allowing data to be transmitted from the transmit shifter. When ROE1 _x = 0, the associated serial data output driver is disabled. When a driver is disabled via the configuration interface, it is internally powered down to reduce device power. If both serial drivers for a channel are in this disabled state, the associated internal logic for that channel is also powered down. A device reset (RESET sampled LOW) disables all output drivers.

Device Configuration Strategy

The following is a series of ordered events needed to load the configuration latches on a per channel basis:

1. Pulse **RESET** Low after device power-up. This operation resets all four channels. Initialize the JTAG state machine to its reset state as detailed in [“JTAG Support” on page 22](#).
2. Set the static latch banks for the target channel.
3. Set the dynamic bank of latches for the target channel. Enable the Receive PLLs and transmit channels. If a receive channel is enabled, set the channel for SMPTE data reception (RXBISTA[1:0] = 01) or BIST data reception (RXBISTA[1:0] = 10).
4. Reset the Phase Alignment Buffer for the target channel. [Optional if phase align buffer is bypassed.]

Table 5. Device Control Latch Configuration Table

ADDR	Channel	Type	DATA6	DATA5	DATA4	DATA3	DATA2	DATA1	DATA0	Reset Value
0 (0000b)	A	S	X	X	X	X	X	0	X	101111
1 (0001b)	A	S	X	X	X	X	0	TXCKSELA	TXRATEA	1010110

14 (1110b)										
15 (1111b)										

JTAG Support

The CYV15G0204TRB contains a JTAG port to allow system level diagnosis of device interconnect. Of the available JTAG modes, boundary scan, and bypass are supported. This capability is present only on the LVTTL inputs and outputs, the REFCLKx± clock inputs, and the TRGCLKx± clock inputs. The high-speed serial inputs and outputs are not part of the JTAG test chain.

To ensure valid device operation after power-up (including non-JTAG operation), the JTAG state machine should also be initialized to a reset state. This should be done in addition to the device reset (using **RESET**). The JTAG state machine can be initialized using **TRST** (asserting it LOW and de-asserting it or leaving it asserted), or by asserting **TMS HIGH** for at least 5

consecutive **TCLK** cycles. This is necessary to ensure that the JTAG controller does not enter any of the test modes after device power-up. In this JTAG reset state, the rest of the device is in normal operation.

Note. The order of device reset (using **RESET**) and JTAG initialization does not matter.

3-Level Select Inputs

Each 3-Level select inputs reports as two bits in the scan register. These bits report the LOW, MID, and HIGH state of the associated input as 00, 10, and 11 respectively

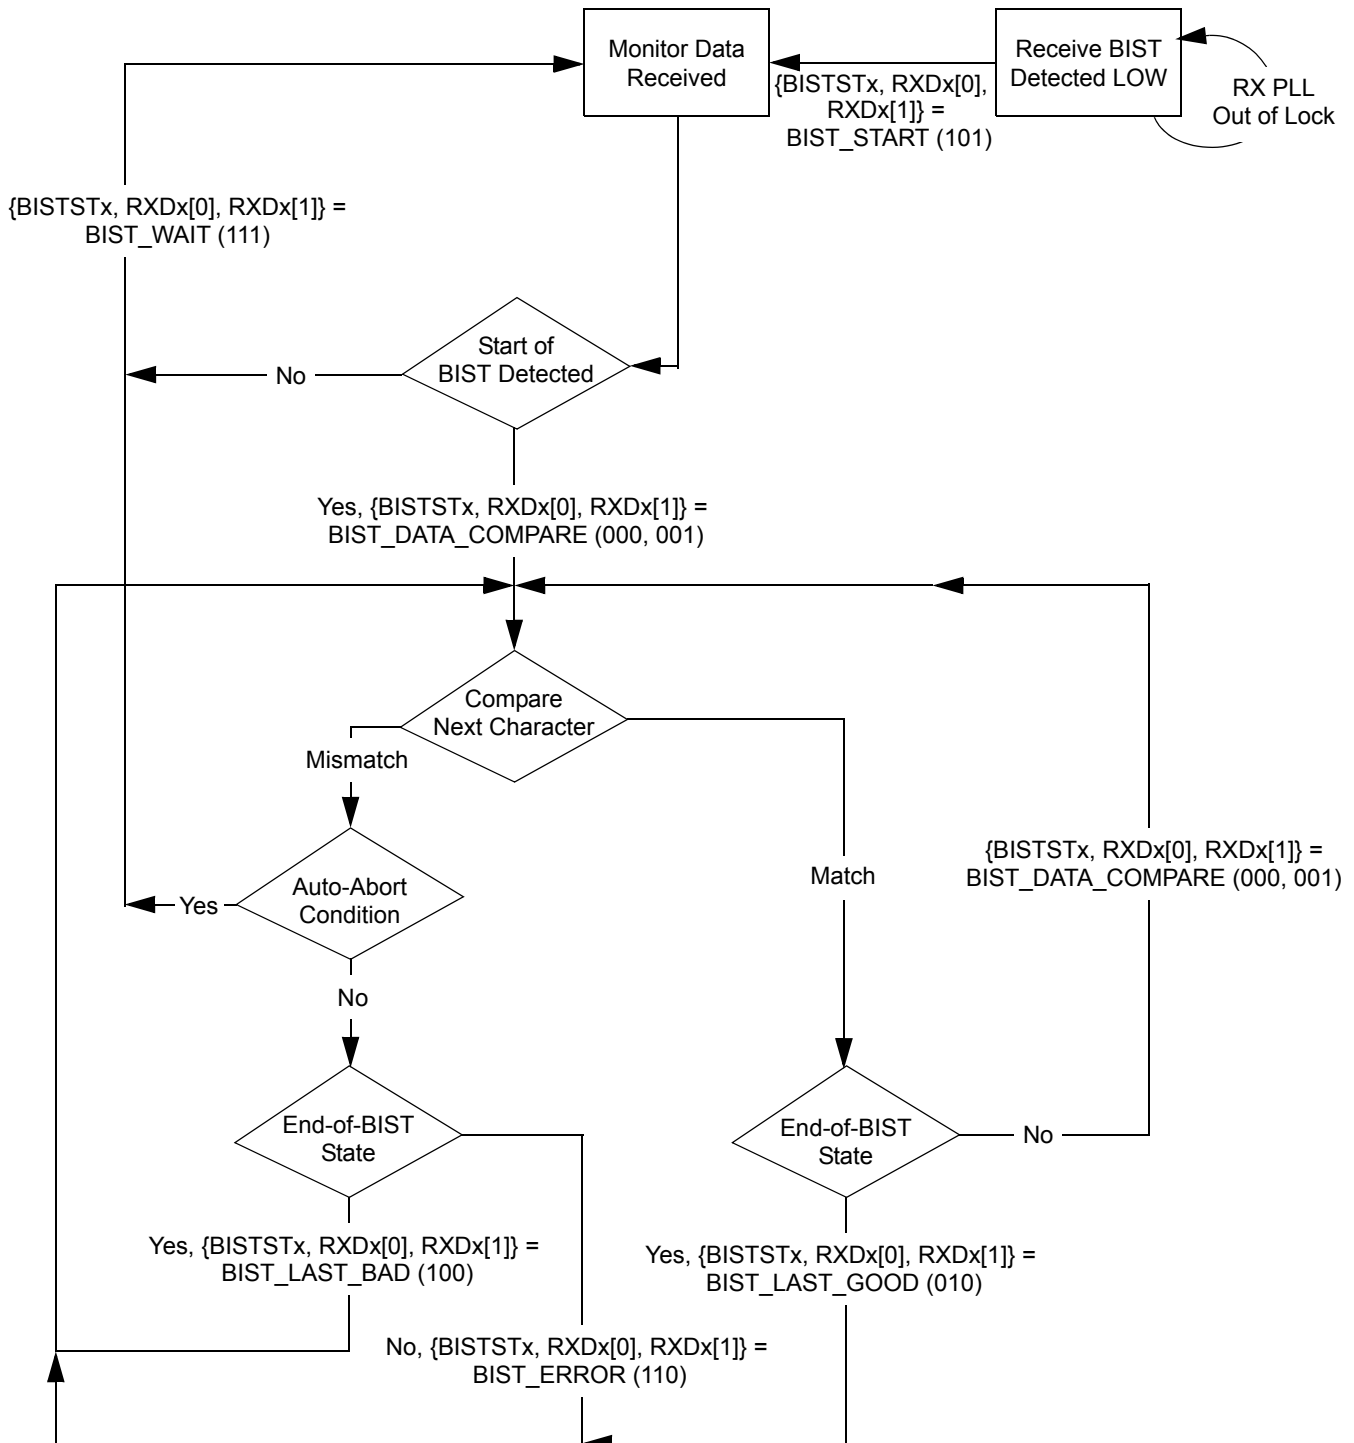

JTAG ID

The JTAG device ID for the CYV15G0204TRB is '0C811069'x

Table 6. Receive Character Status Bits

{BISTSTx, RXDx[0], RXDx[1]}	Description
	Receive BIST Status (Receive BIST = Enabled)
000, 001	BIST Data Compare. Character compared correctly.
010	BIST Last Good. Last Character of BIST sequence detected and valid.
011	Reserved.
100	BIST Last Bad. Last Character of BIST sequence detected invalid.
101	BIST Start. Receive BIST is enabled on this channel, but character compares have not yet commenced. This also indicates a PLL Out of Lock condition.
110	BIST Error. While comparing characters, a mismatch was found in one or more of the character bits.
111	BIST Wait. The receiver is comparing characters. but has not yet found the start of BIST character to enable the LFSR.

Figure 2. Receive BIST State Machine

Maximum Ratings

Exceeding maximum ratings may shorten the useful life of the device. User guidelines are not tested.

Storage temperature	-65 °C to +150 °C
Ambient temperature with power applied	-55 °C to +125 °C
Supply voltage to ground potential	-0.5 V to +3.8 V
DC voltage applied to LVTTTL outputs in high-Z state	-0.5 V to $V_{CC} + 0.5 V$
Output current into LVTTTL outputs (LOW)	60 mA
DC input voltage	-0.5 V to $V_{CC} + 0.5 V$

Static discharge voltage..... > 2000 V
(per MIL-STD-883, Method 3015)

Latch-up current

Power-up Requirements

The CYV15G0204TRB requires one power-supply. The Voltage on any input or I/O pin cannot exceed the power pin during power-up.

Operating Range

Range	Ambient Temperature	V_{CC}
Commercial	0 °C to +70 °C	+3.3 V $\pm 5\%$

CYV15G0204TRB DC Electrical Characteristics

Parameter	Description	Test Conditions	Min	Max	Unit
LVTTTL-compatible Outputs					
V_{OHT}	Output HIGH Voltage	$I_{OH} = -4 \text{ mA}$, $V_{CC} = \text{Min}$	2.4	-	V
V_{OLT}	Output LOW Voltage	$I_{OL} = 4 \text{ mA}$, $V_{CC} = \text{Min}$	-	0.4	V
I_{OST}	Output Short Circuit Current	$V_{OUT} = 0 \text{ V}^{[12]}$, $V_{CC} = 3.3 \text{ V}$	-20	-100	mA
I_{OZL}	High-Z Output Leakage Current	$V_{OUT} = 0 \text{ V}$, V_{CC}	-20	20	μA
LVTTTL-compatible Inputs					
V_{IHT}	Input HIGH Voltage		2.0	$V_{CC} + 0.3$	V
V_{ILT}	Input LOW Voltage		-0.5	0.8	V
I_{IHT}	Input HIGH Current	REFCLKx Input, $V_{IN} = V_{CC}$	-	1.5	mA
		Other Inputs, $V_{IN} = V_{CC}$	-	+40	μA
I_{ILT}	Input LOW Current	REFCLKx Input, $V_{IN} = 0.0 \text{ V}$	-	-1.5	mA
		Other Inputs, $V_{IN} = 0.0 \text{ V}$	-	-40	μA
I_{IHPDT}	Input HIGH Current with internal pull-down	$V_{IN} = V_{CC}$	-	+200	μA
I_{ILPUT}	Input LOW Current with internal pull-up	$V_{IN} = 0.0 \text{ V}$	-	-200	μA
LVDIFF Inputs: REFCLKx±					
$V_{DIFF}^{[13]}$	Input Differential Voltage		400	V_{CC}	mV
V_{IHHP}	Highest Input HIGH Voltage		1.2	V_{CC}	V
V_{ILLP}	Lowest Input LOW voltage		0.0	$V_{CC}/2$	V
$V_{COMREF}^{[14]}$	Common Mode Range		1.0	$V_{CC} - 1.2 \text{ V}$	V
3-Level Inputs					
V_{IHH}	Three-Level Input HIGH Voltage	$\text{Min} \leq V_{CC} \leq \text{Max}$	$0.87 * V_{CC}$	V_{CC}	V
V_{IMM}	Three-Level Input MID Voltage	$\text{Min} \leq V_{CC} \leq \text{Max}$	$0.47 * V_{CC}$	$0.53 * V_{CC}$	V
V_{ILL}	Three-Level Input LOW Voltage	$\text{Min} \leq V_{CC} \leq \text{Max}$	0.0	$0.13 * V_{CC}$	V
I_{IHH}	Input HIGH Current	$V_{IN} = V_{CC}$	-	200	μA
I_{IMM}	Input MID current	$V_{IN} = V_{CC}/2$	-50	50	μA
I_{ILL}	Input LOW current	$V_{IN} = \text{GND}$	-	-200	μA

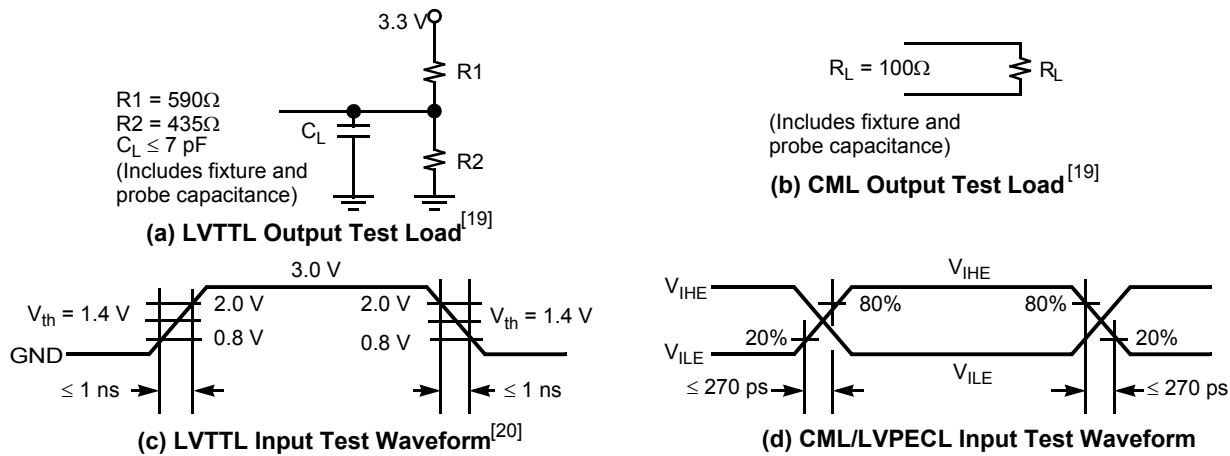

Notes

- Tested one output at a time, output shorted for less than one second, less than 10% duty cycle.
- This is the minimum difference in voltage between the true and complement inputs required to ensure detection of a logic-1 or logic-0. A logic-1 exists when the true (+) input is more positive than the complement (-) input. A logic-0 exists when the complement (-) input is more positive than true (+) input.
- The common mode range defines the allowable range of REFCLKx+ and REFCLKx- when REFCLKx+ = REFCLKx-. This marks the zero-crossing between the true and complement inputs as the signal switches between a logic-1 and a logic-0.

CYV15G0204TRB DC Electrical Characteristics (continued)

Parameter	Description	Test Conditions	Min	Max	Unit	
Differential CML Serial Outputs: TOUTA1±, TOUTA2±, TOUTB1±, TOUTB2±, ROUTC1±, ROUTC2±, ROUTD1±, ROUTD2±						
V _{OHC}	Output HIGH Voltage (V _{CC} Referenced)	100 Ω differential load	V _{CC} - 0.5	V _{CC} - 0.2	V	
		150 Ω differential load	V _{CC} - 0.5	V _{CC} - 0.2	V	
V _{OLC}	Output LOW Voltage (V _{CC} Referenced)	100 Ω differential load	V _{CC} - 1.4	V _{CC} - 0.7	V	
		150 Ω differential load	V _{CC} - 1.4	V _{CC} - 0.7	V	
V _{ODIF}	Output Differential Voltage (OUT+) - (OUT-)	100 Ω differential load	450	900	mV	
		150 Ω differential load	560	1000	mV	
Differential Serial Line Receiver Inputs: INC1±, INC2±, IND1±, IND2±						
V _{DIFFs} ^[15]	Input Differential Voltage (IN+) - (IN-)		100	1200	mV	
V _{IHE}	Highest Input HIGH Voltage			V _{CC}	V	
V _{ILE}	Lowest Input LOW Voltage		V _{CC} - 2.0		V	
I _{IHE}	Input HIGH Current	V _{IN} = V _{IHE} Max		1350	μA	
I _{ILE}	Input LOW Current	V _{IN} = V _{ILE} Min	-700		μA	
V _{COM} ^[16]	Common Mode input range	((V _{CC} - 2.0 V) + 0.5) min, (V _{CC} - 0.5 V) Max	+1.25	+3.1	V	
Power Supply			Typ	Max		
I _{CC} ^[17, 18]	Max Power Supply Current	REFCLKx = MAX	Commercial	810	990	mA
I _{CC} ^[17, 18]	Typical Power Supply Current	REFCLKx = 125 MHz	Commercial	770	950	mA

AC Test Loads and Waveforms

Notes

15. This is the minimum difference in voltage between the true and complement inputs required to ensure detection of a logic-1 or logic-0. A logic-1 exists when the true (+) input is more positive than the complement (-) input. A logic-0 exists when the complement (-) input is more positive than true (+) input.
16. The common mode range defines the allowable range of INPUT+ and INPUT- when INPUT+ = INPUT-. This marks the zero-crossing between the true and complement inputs as the signal switches between a logic-1 and a logic-0.
17. Maximum I_{CC} is measured with V_{CC} = MAX, T_A = 25 °C, with all channels and Serial Line Drivers enabled, sending a continuous alternating 01 pattern, and outputs unloaded.
18. Typical I_{CC} is measured under similar conditions except with V_{CC} = 3.3 V, T_A = 25 °C, with all channels enabled and one Serial Line Driver per transmit channel sending a continuous alternating 01 pattern. The redundant outputs on each channel are powered down and the parallel outputs are unloaded.
19. Cypress uses constant current (ATE) load configurations and forcing functions. This figure is for reference only.
20. The LVTTTL switching threshold is 1.4 V. All timing references are made relative to where the signal edges cross the threshold voltage.
