

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# Multiprotocol Dual Smart Card Interface

## General Description

The DS8007 multiprotocol dual smart card interface is a low-cost, dual smart card reader interface supporting all ISO 7816, EMV®, and GSM11-11 requirements. Through its 8-bit parallel bus and dedicated address selects (AD3–AD0), the DS8007 can easily and directly connect to the nonmultiplexed byte-wide bus of a Maxim secure microcontroller. Optionally, the parallel bus can be multiplexed to allow direct access to the multiplexed bus of an 80C51-compatible microcontroller through MOVX memory addressing.

One integrated ISO 7816 UART is multiplexed among the interfaces to allow high-speed automatic smart card processing with each card-possessing, independent, variable, baud-rate capability. The card interface is controlled by internal sequencers that support automatic activation and deactivation sequencing, handling all actions required for T = 0, T = 1, and synchronous protocols. Emergency deactivation is also supported in case of supply dropout. A third card is supported through the auxiliary I/O. The same set of I/O can optionally be used as additional serial interface for the UART.

The DS8007 provides all electrical signals necessary to interface with two smart cards. The integrated voltage converter ensures full cross-compatibility between 1.8V/3V/5V cards and a 1.8V/3V/5V environment, and allows operation within a 2.7V to 6V supply voltage range.

## Applications

Banking Applications (Point-of-Sale Terminals, Debit/Credit Payment Terminals, PIN Pads, Automated Teller Machines)

Telecommunications

Pay Television

Access Control

## Ordering Information

PART	TEMP RANGE	SMART CARDS SUPPORTED	PIN-PACKAGE
DS8007-ENG	-40°C to +85°C	2 + auxiliary	48 LQFP
DS8007-ENG+	-40°C to +85°C	2 + auxiliary	48 LQFP

+Denotes a lead(Pb)-free/RoHS-compliant package.

EMV is a registered trademark of EMVCo LLC.

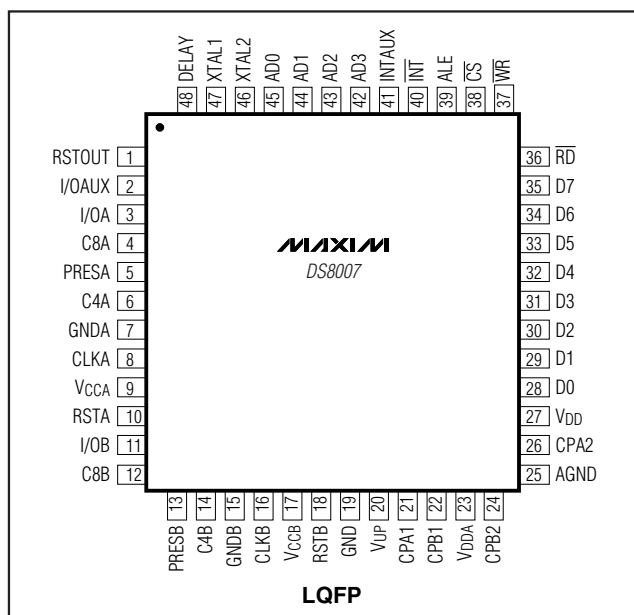

MAXQ is a registered trademark of Maxim Integrated Products, Inc.

**Note:** Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device may be simultaneously available through various sales channels. For information about device errata, go to: [www.maxim-ic.com/errata](http://www.maxim-ic.com/errata).

## Features

- ◆ Integrated ISO 7816 UART Provides Complete Interface/Control for Two Separate Smart Card Devices
- ◆ 8kV (min) ESD Protection on Card Interfaces
- ◆ Internal IC Card Supply Voltage Generation
  - 5.0V ±5%, 65mA (max)
  - 3.0V ±8%, 50mA (max)
  - 1.8V ±10%, 30mA (max)
- ◆ Automatic Card Activation, Deactivation, and Data Communication Controlled by Dedicated Internal Sequencer
- ◆ Host Interface Through an 8-Bit Parallel Bus (User-Selectable Multiplexed or Nonmultiplexed Modes)
- ◆ Chip Select and Three-State Bus Allow Multiple Devices (Card Readers and Memories) on Bus
- ◆ 8-Character Receive FIFO with Optional Programmable Depth/Threshold
- ◆ I/O Interface Pin to External ISO 7816 UART for Auxiliary Interface
- ◆ Separate Card Clock Generation (Up to 10MHz) with 2x Frequency Doubling
- ◆ Selectable Card Clock Stop High, Stop Low, or Internally Generated 1.25MHz (for Card Power-Down)
- ◆ EMV-Certified Reference Design and Evaluation Kit Available (DS8007-KIT)

## Pin Configuration

Typical Operating Circuit appears at end of data sheet.

# Multiprotocol Dual Smart Card Interface

## ABSOLUTE MAXIMUM RATINGS

Voltage Range on V<sub>DD</sub> Relative to Ground .....-0.5V to +6.5V  
 Voltage Range on V<sub>DDA</sub> Relative to Ground .....-0.5V to +6.5V  
 Voltage Range on Any Pin Relative to Ground  
 Pins CPA1, CPA2, CPB1, CPB2, and V<sub>UP</sub> .....-0.5V to +7.5V  
 All Other Pins .....-0.5V to (V<sub>DD</sub> + 0.5V)  
 Maximum Junction Temperature .....+150°C

Continuous Power Dissipation (T<sub>A</sub> = +70°C)  
 LQFP Multilayer Board  
 (derate 22mW/°C above +70°C) .....1782mW  
 Operating Temperature Range .....-40°C to +85°C  
 Storage Temperature Range .....-65°C to +150°C  
 Lead Temperature (soldering, 10s) .....+300°C  
 Soldering Temperature (reflow) .....+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

(V<sub>DD</sub> = +3.3V, V<sub>DDA</sub> = +3.3V, T<sub>A</sub> = +25°C, unless otherwise noted.) (Note 1)

PARAMETER		SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Digital Supply Voltage		V <sub>DD</sub>		2.7		6.0	V
Step-Up Converter Supply Voltage		V <sub>DDA</sub>		V <sub>DD</sub>		6.0	V
Power-Down V <sub>DD</sub> Current	Cards Inactive	I <sub>PD</sub>	f <sub>XTAL</sub> = 0MHz			0.9	mA
	Cards Active		f <sub>XTAL</sub> = 0MHz, f <sub>CLK</sub> = 0MHz, V <sub>CCx</sub> = 5V			2.2	
Sleep Mode V <sub>DD</sub> Current (Cards Active)		I <sub>STOP</sub>	f <sub>CLK</sub> = 0MHz, V <sub>CCx</sub> = 5V			24	mA
Active V <sub>DD</sub> Current 5V Cards		I <sub>DD</sub>	3x V <sub>DD</sub> step-up: I <sub>CCA</sub> + I <sub>CCB</sub> = 80mA, V <sub>DD</sub> = 2.7V, f <sub>XTAL</sub> = 20MHz, f <sub>CLK</sub> = 10MHz			325	mA
Active V <sub>DD</sub> Current 3V Cards		I <sub>DD</sub>	2x V <sub>DD</sub> step-up: I <sub>CCA</sub> + I <sub>CCB</sub> = 80mA, f <sub>XTAL</sub> = 20MHz, f <sub>CLK</sub> = 10MHz, V <sub>DD</sub> = 2.7V			225	mA
			No step-up: I <sub>CCA</sub> + I <sub>CCB</sub> = 80mA, f <sub>XTAL</sub> = 20MHz, f <sub>CLK</sub> = 10MHz, V <sub>DD</sub> = 5V			120	
Power-Fail Reset Voltage		V <sub>RST</sub>	Threshold voltage (falling)	2.1		2.5	V
		V <sub>HYS</sub>	Hysteresis	50		170	mV
Delay Pin	Reset Threshold	V <sub>D_RST</sub>			1.25		V
	Output Voltage	V <sub>DO</sub>				V <sub>DD</sub> + 0.3	
	Output Current	I <sub>DO</sub>	V <sub>DELAY</sub> = 0V			-2	μA
			V <sub>DELAY</sub> = V <sub>DD</sub>			+2	mA
Output Capacitance	C <sub>DO</sub>			1		nF	
<b>RSTOUT PIN</b>							
Output High Voltage		V <sub>OHRSTO</sub>	I <sub>OH</sub> = -1mA	0.8 x V <sub>DD</sub>		V <sub>DD</sub> + 0.3	V
Output Low Voltage		V <sub>OLRSTO</sub>	I <sub>OL</sub> = 2mA	-0.3		+0.4	V
Leakage Current		I <sub>L</sub>	V <sub>OL</sub> = 0V, V <sub>OH</sub> = 5V	-10		+10	μA

## Pin Description

DS8007

PIN	NAME	FUNCTION
1	RSTOUT	Reset Output. This active-high output is provided for resetting external devices. The RSTOUT pin is driven high until the DELAY pin reaches $V_{DRST}$ . Once the DELAY pin reaches $V_{DRST}$ , the RSTOUT pin is three-stated so it can externally be pulled down. The SUPL bit is set for each RSTOUT pulse.
2	I/OAUX	Auxiliary I/O. This I/O pin allows connection to an auxiliary smart card interface.
3	I/OA	Smart Card A I/O Data Line. This is the I/O data line associated with smart card A. This is also referred to as the ISO C7 contact.
4	C8A	Smart Card A Auxiliary I/O. This is an auxiliary I/O associated with smart card A. This is also referred to as the ISO C8 contact. This can be associated with synchronous cards.
5	PRESA	Smart Card A Presence Contact. This is the active-high presence contact associated with smart card A.
6	C4A	Smart Card A Auxiliary I/O. This is an auxiliary I/O associated with smart card A. This is also referred to as the ISO C4 contact. This can be associated with synchronous cards.
7	GNDA	Smart Card A Ground. This must be connected to GND.
8	CLKA	Smart Card A Clock Output. This is the clock output associated with smart card A. This is also referred to as the ISO C3 contact.
9	VCCA	Smart Card A Supply Voltage. This is the supply voltage output associated with smart card A. This is also referred to as the ISO C1 contact.
10	RSTA	Smart Card A Reset. This is the reset output associated with smart card A. This is also referred to as the ISO C2 contact.
11	I/OB	Smart Card B I/O Data Line. This is the I/O data line associated with smart card B. This is also referred to as the ISO C7 contact.
12	C8B	Smart Card B Auxiliary I/O. This is an auxiliary I/O associated with smart card B. This is also referred to as the ISO C8 contact. This can be associated with synchronous cards.
13	PRESB	Smart Card B Presence Contact. This is the active-high presence contact associated with smart card B.
14	C4B	Smart Card B Auxiliary I/O. This is an auxiliary I/O associated with smart card B. This is also referred to as the ISO C4 contact. This can be associated with synchronous cards.
15	GNDB	Smart Card B Ground. This must be connected to GND.
16	CLKB	Smart Card B Clock Output. This is the clock output associated with smart card B. This is also referred to as the ISO C3 contact.
17	VCCB	Smart Card B Supply Voltage. This is the supply voltage output associated with smart card B. This is also referred to as the ISO C1 contact.
18	RSTB	Smart Card B Reset. This is the reset output associated with smart card B. This is also referred to as the ISO C2 contact.
19	GND	Ground
20	V <sub>UP</sub>	Step-Up Converter Connection. Connect a low-ESR capacitor of 220nF between this pin and ground.
21	CPA1	Step-Up Converter Contact 1. Connect a low-ESR capacitor of 220nF between CPA1 and CPA2.
22	CPB1	Step-Up Converter Contact 3. Connect a low-ESR capacitor of 220nF between CPB1 and CPB2.
23	V <sub>DDA</sub>	Analog Supply Voltage. Positive analog-supply voltage for the step-up converter; can be higher but not lower than $V_{DD}$ . This pin should be decoupled to AGND with a good quality capacitor.

# Multiprotocol Dual Smart Card Interface

## Pin Description (continued)

PIN	NAME	FUNCTION
24	CPB2	Step-Up Converter Contact 4. Connect a low-ESR capacitor of 220nF between CPB1 and CPB2.
25	AGND	Analog Ground
26	CPA2	Step-Up Converter Contact 2. Connect a low-ESR capacitor of 220nF between CPA1 and CPA2.
27	V <sub>DD</sub>	Digital Supply Voltage. This pin should be decoupled to GND with a good quality capacitor.
28–35	D0–D7	8-Bit Digital I/O. This port functions as the data or address/data communication lines between the host controller and the DS8007 for the nonmultiplexed and multiplexed operating modes, respectively.
36	$\overline{RD}$	Active-Low Parallel Bus Read Strobe Input. In multiplexed mode, this input indicates when the host processor is reading information from the DS8007. In nonmultiplexed mode, this pin signals the current operation is a read ( $RD = 1$ ) or a write ( $RD = 0$ ) when $CS$ and $WR$ are low.
37	$\overline{WR}$	Active-Low Parallel Bus Write Strobe Input. In multiplexed mode, this input indicates when the host processor is writing information to the DS8007. In nonmultiplexed mode, a low on this pin signals the bus is engaged in a read or write operation.
38	$\overline{CS}$	Active-Low Chip-Select Input. This input indicates when the DS8007 is active on the parallel bus.
39	ALE	Address Latch Enable Input. This signal monitors the ALE signal when the host processor bus is operating in multiplexed mode. Connect this signal to V <sub>DD</sub> when operating in nonmultiplexed mode.
40	$\overline{INT}$	Active-Low Interrupt. This output indicates an interrupt is active.
41	INTAUX	Auxiliary Interrupt Input. This pin serves as an auxiliary interrupt.
42–45	AD3–AD0	Register Selection Address Inputs. These pins function as the address input lines for the nonmultiplexed configuration and should be connected to ground or V <sub>DD</sub> in the multiplexed configuration.
46, 47	XTAL2, XTAL1	Crystal Oscillators. Place a crystal with appropriate load capacitors between these pins if that is the desired clock source. XTAL1 also acts as an input if there is an external clock source in place of a crystal.
48	DELAY	External Delay Capacitor Connection. Connect a capacitor from this pin to ground to set the power-on reset delay.

# Multiprotocol Dual Smart Card Interface

## Detailed Description

The following describes the major functional features of the device. Use of this document requires the reader have a basic understanding of ISO 7816 terminology.

## Parallel Bus Interface

The device interfaces to a host computer/processor through a multiplexed or demultiplexed, parallel, 8-bit data bus (D0–D7). The parallel bus interface monitors the ALE signal and automatically detects whether a multiplexed or nonmultiplexed external bus interface is intended. The nonmultiplexed external bus interface is the default configuration and is maintained so long as

no edge (activity) is detected on the ALE pin. Once a rising edge is detected on the ALE pin, the DS8007 is placed into the multiplexed mode of operation. Once in the multiplexed mode of operation, a reset/power cycle or the deassertion of  $\overline{CS}$  forces the device to the nonmultiplexed mode. Connecting the ALE pin to  $V_{DD}$  or ground forces the device into nonmultiplexed parallel bus mode. Figure 7 shows that the bus recognition dictates whether the external address lines (AD3–AD0) can be used directly or whether the external data lines (D7–D0) must be latched according to the ALE input signal. In the multiplexed mode of operation, a new address is latched irrespective of the state of  $\overline{CS}$ .

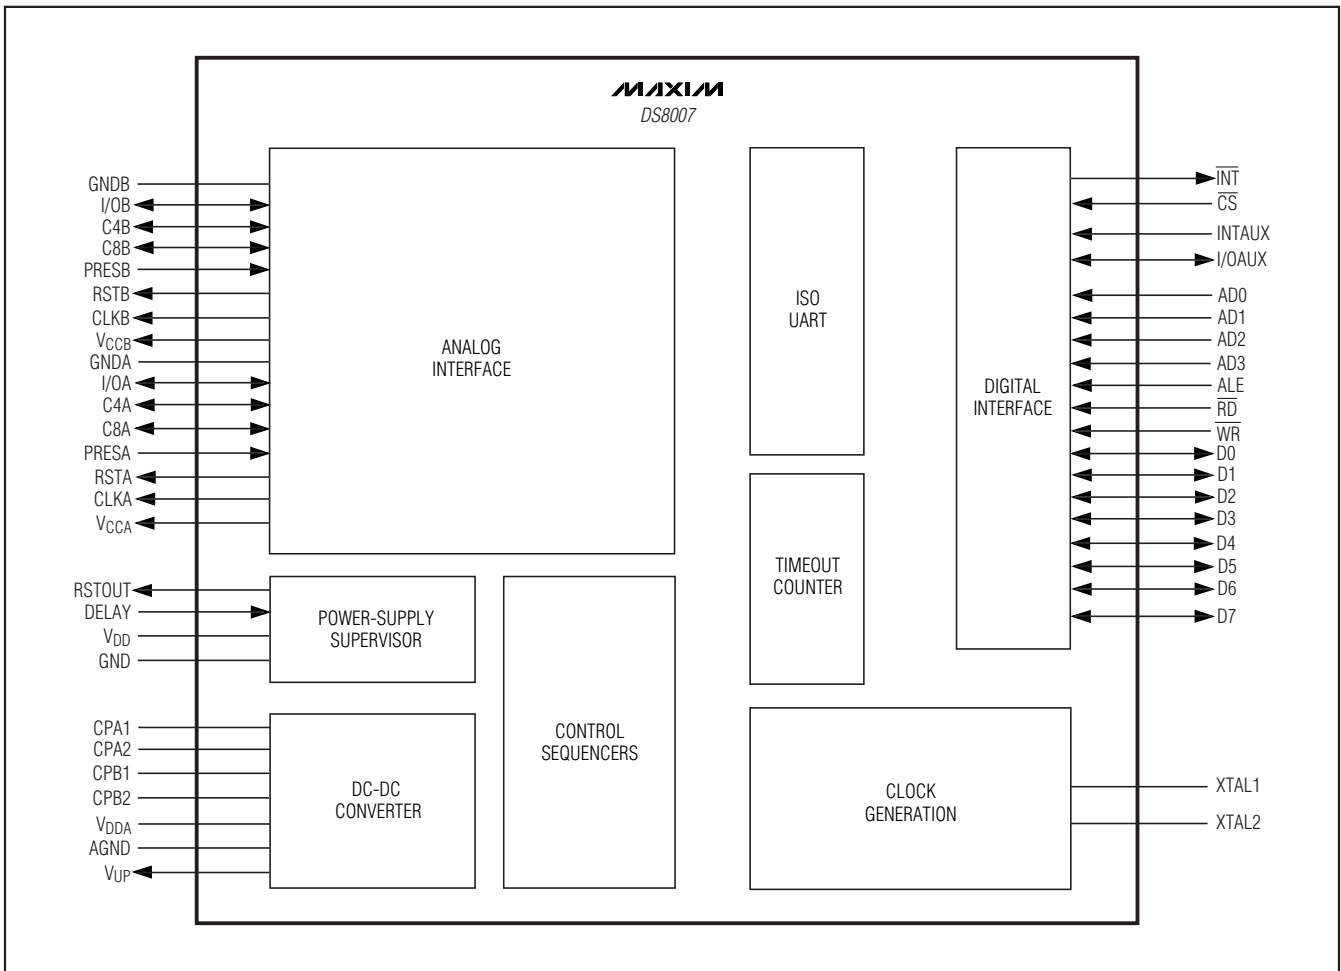

Figure 6. Block Diagram

## Multiprotocol Dual Smart Card Interface

Figure 7. Parallel Bus Interface

### Multiplexed Mode

In the multiplexed mode of operation, the D7–D0 signals are multiplexed between address and data. The falling edge of the address latch enable (ALE) signal from the host microcontroller latches the address (D3–D0), and the  $\overline{RD}$  and  $\overline{WR}$  strobe input signals are used to enable a read or write operation, respectively, if the DS8007 is selected (i.e.,  $\overline{CS} = 0$ ). See the AC timing for the multiplexed parallel bus mode found earlier in this data sheet.

### Nomultiplexed Mode

In the nonmultiplexed mode of operation, the address is always provided on the AD3–AD0 signals, and the data is always transacted on the D7–D0 signals. The  $\overline{RD}$  input signal is used as a read/write (R/W) operation select. The  $\overline{WR}$  and  $\overline{CS}$  input signals serve as active-low enables, and must be asserted for the read or write operation to take place. See the AC timing for the nonmultiplexed parallel bus mode found earlier in this data sheet.

# Multiprotocol Dual Smart Card Interface

## Control Registers

Special control registers that the host computer/micro-controller accesses through the parallel bus manage most DS8007 features. Many of the registers, although only mentioned once in the listing, are duplicated for each card interface. The PDR, GTR, UCR1, UCR2, and CCR registers exist separately for each of the three card interfaces. The PCR register is provided only for card interface A and card interface B.

The specific register to be accessed is controlled by the current setting of the SC3–SC1 bits in the Card Select Register. For example, there are three instances of the UART Control Register 1 (UCR1) at address 06h.

If the SC3–SC1 bits are configured so that card A is selected, then all reads and writes to address 06h only affect card A. If SC3–SC1 are changed to select card B, then all reads and writes to address 06h only affect card B, etc.

In addition, some registers have different functions based on whether the register is being read from or written to. An example of this are the UART Receive (URR)/UART Transmit (UTR) registers located at address 0Dh. Although they share the same address, during read operations the receive register is read, and write operations go to a separate transmit register. This selection requires no extra configuration by the software.

**Table 1. Special Function Register Map**

ADDRESS (HEX)	REGISTER NAME	R/W	BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0	RESET	$\overline{RIU} = 0^*$

\*u = unchanged, x = always reflects state of external device pin, even when  $\overline{RIU} = 0$ .

**Note:** Writes to unimplemented bits have no effect. Reads of unimplemented bits return 0.

# Multiprotocol Dual Smart Card Interface

## Card Select Register (CSR)

	7	6	5	4	3	2	1	0
Address 00h	CSR7	CSR6	CSR5	CSR4	RIU	SC3	SC2	SC1
	R-0	R-0	R-1	R-1	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 00110uuub on  $\overline{RIU} = 0$ .

**Bits 7 to 4: Identification Bits (CSR7 to CSR4).** These bits provide a method for software to identify the device as follows:

0011 = DS8007 revision Ax

**Bit 3: Reset ISO UART ( $\overline{RIU}$ ).** When this bit is cleared (0), most of the ISO UART registers are reset to their initial values. This bit must be cleared for at least 10ns prior to initiating an activation sequence. This bit must be set (1) by software before any action on the UART can take place.

**Bits 2 to 0: Select Card Bits (SC3 to SC1).** These bits determine which IC card interface is active as shown below. Only one bit should be active at any time, and no card is selected after reset (i.e., SC3–SC1 = 000b). Other combinations are invalid.

000 = No card is selected.

001 = Card A is selected.

010 = Card B is selected.

100 = AUX card interface is selected.

## Clock Configuration Register (CCR)

	7	6	5	4	3	2	1	0
Address 01h	—	—	SHL	CST	SC	AC2	AC1	AC0
	R-0	R-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 00uuuuuub on  $\overline{RIU} = 0$ .

**Bits 7 and 6: Reserved.**

**Bit 5: Stop High or Low (SHL).** This bit determines if the card clock stops in the low or high state when the CST bit is active. It forces the clock to stop in a low state when SHL = 0 or in a high state when SHL = 1.

**Bit 4: Clock Stop (CST).** For an asynchronous card, this bit allows the clock to the selected card to be stopped. When this bit is set (1), the card clock is stopped in the state determined by the SHL bit. When this bit is cleared (0), the card clock operation is defined by CCR bits AC2–AC0.

**Bit 3: Synchronous Clock (SC).** For a synchronous card, the card clock is controlled by software manipulation of this SC, and the contact CLKx is the copy of the value in this bit. In synchronous transmit mode, a write to the UTR results in the least significant bit (LSb) of the data written to the UTR being driven out on the

I/Ox pin. In synchronous receive mode, the state of the I/Ox pin can be read from the LSb of the URR.

**Bits 2 to 0: Alternating Clock Select (AC2 to AC0).** These bits select the frequency of the clock provided to the active card interface and to the UART for the elementary time unit (ETU) generation as shown below. All frequency changes are synchronous so that there are no spikes or unwanted pulse widths during transitions.  $f_{INT}$  is the frequency of the internal oscillator.

AC2–AC0

000 =  $f_{XTAL}$

001 =  $f_{XTAL} / 2$

010 =  $f_{XTAL} / 4$

011 =  $f_{XTAL} / 8$

1xx =  $f_{INT} / 2$

# Multiprotocol Dual Smart Card Interface

## Programmable Divider Register (PDR)

	7	6	5	4	3	2	1	0
Address 02h	PD7	PD6	PD5	PD4	PD3	PD2	PD1	PD0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset; all bits unaffected by  $\overline{RIU} = 0$ .

**Bits 7 to 0: Programmable ETU Divider Register Bits 7 to 0 (PD7 to PD0).** These bits, in conjunction with the defined UART input clock (based upon CKU, AC2-AC0) and the prescaler selection (PSC bit), are used to define the ETU for the UART when interfaced to the associated card interface. The output of the prescaler block is further divided according to the PD7-PD0 bits as follows:

- ETU = Prescaler output / (PD7-PD0), when PD7-PD0 = 02h-FFh
- ETU = Prescaler output / 1, when PD7-PD0 = 00h-01h
- Prescaler output / 256 is not supported

## UART Control Register 2 (UCR2)

	7	6	5	4	3	2	1	0
Address 03h	—	DISTBE/RBF	DISAUX	PDWN	SAN	$\overline{AUTOC}$	CKU	PSC
	R-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset; all bits unaffected by  $\overline{RIU} = 0$ .

**Bit 7: Reserved.**

**Bit 6: Disable TBE/RBF Interrupt (DISTBE/RBF).** This bit controls whether the TBE/RBF flag can generate an interrupt on the  $\overline{INT}$  pin. When this bit is cleared to 0, an interrupt is signaled on the  $\overline{INT}$  pin in response to the TBE/RBF flag getting set. When DISTBE/RBF is set to 1, interrupts are not generated in response to the TBE/RBF flag. Disabling the TBE/RBF interrupt can allow faster communication speed with the card, but requires that a copy of TBE/RBF in register MSR be polled to not lose priority interrupts that can occur in register USR.

**Bit 5: Disable Auxiliary Interrupt (DISAUX).** This bit controls whether the external INTAUX pin can generate an interrupt on the  $\overline{INT}$  output pin. When this bit is cleared to 0, a change on the INTAUX input pin results in assertion of the  $\overline{INT}$  output pin. When DISAUX is set to 1, a change on INTAUX does not result in assertion of the  $\overline{INT}$  output pin. The INTAUXL bit is set by a change on the INTAUX pin independent of the DISAUX bit state. Since the INTAUX bit is set independent of the DISAUX bit, it is advisable to read HSR (thus clearing INTAUX) prior to clearing DISAUX to avoid an interrupt on the  $\overline{INT}$  pin. To avoid an interrupt when selecting a different card, the DISAUX bit should be set to 1 in all UCR2 registers.

# Multiprotocol Dual Smart Card Interface

**Bit 4: Power-Down Mode Enable (PDWN).** This bit controls entry into the power-down mode. Power-down mode can only be entered if the SUPL bit has been cleared. When PDWN is set to 1, the XTAL1 and XTAL2 crystal oscillator is stopped, and basic functions such as the sequencers are supported by the internal ring oscillator. The UART is put in a suspended state, and the clocks to the UART, the ETU unit, and the timeout counter are gated off. During the power-down mode, it is not possible to select a card other than the one currently selected (advisory to the programmer, selecting another card during power-down mode is not recommended). There are five ways of exiting the power-down mode:

- Insertion of card A or card B (detected by PRLA or PRLB).
- Withdrawal of card A or card B (detected by PRLA or PRLB).
- Reassertion of the  $\overline{CS}$  pin to select the DS8007 ( $\overline{CS}$  must be deasserted after setting PDWN = 1 for this event to exit from power-down).
- INTAUXL bit is set due to change in INTAUX (INTAUXL bit must be cleared first).
- Clearing of PDWN bit by software (if  $\overline{CS}$  pin is always tied to 0).

Except in the case of a read operation of register HSR, the  $\overline{INT}$  pin remains asserted in the active-low state. The host device can read the status registers after the oscillator warmup time, and the  $\overline{INT}$  signal returns to the high state.

**Bit 3: Synchronous/Asynchronous Card Select (SAN).** This bit selects whether a synchronous or asynchronous card interface is enabled. When this bit is cleared to 0, an asynchronous card interface is expected. When this bit is set to 1, a synchronous interface is expected. In synchronous mode, the UART is bypassed; the SC bit controls the CLK, and I/O is transacted in the LSb of UTR/URR. Card interface AUX cannot operate in the true synchronous mode since it does not have a CLK signal to accompany I/OAUX. However, the SAN bit invokes the same control of I/OAUX through UTR/URR as is given for card interfaces A and B.

**Bit 2: Auto Convention Disable ( $\overline{AUTOC}$ ).** This active-low bit controls whether the decoding convention should automatically be detected during the first received character in answer-to-reset (ATR). If  $\overline{AUTOC}$  = 0, the character decoding convention is automatically detected (while SS = 1) and the UCR1.CONV bit is written accordingly by hardware. If  $\overline{AUTOC}$  = 1, the UCR1.CONV bit must be set by software to assign the character decoding convention. The  $\overline{AUTOC}$  bit must not be changed during a card session.

**Bit 1: Clock UART Doubler Enable (CKU).** This bit enables the effective ETU defined for the UART to last half the number of clock cycles defined by the AC2-AC0 and PD7-PD0 configuration (except in the case when AC2-AC0 = 000b, where  $f_{CLK} = f_{XTAL}$ ). When CKU is cleared to 0, the AC2-AC0 defined  $f_{CLK}$  is used for ETU timing generation. When CKU is set to 1, a clock frequency of  $2 \times f_{CLK}$  is used for ETU generation.

**Bit 0: Prescaler Select (PSC).** When PSC = 0, the prescaler value is 31. When PSC = 1, the prescaler value is 32.

## Guard Time Register (GTR)

	7	6	5	4	3	2	1	0
Address 05h	GTR.7	GTR.6	GTR.5	GTR.4	GTR.3	GTR.2	GTR.1	GTR.0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset; all bits unaffected by  $\overline{RIU} = 0$ .

**Bits 7 to 0: Guard Time Register Bits 7 to 0 (GTR.7 to GTR.0).** These bits are used for storing the number of guard time units (ETU) requested during ATR. When

transmitting, the DS8007 UART delays these numbers of extra guard time ETU before transmitting a character written to UTR.

# Multiprotocol Dual Smart Card Interface

## UART Control Register 1 (UCR1)

DS8007

Address 06h	7	6	5	4	3	2	1	0
	FTE0	FIP	—	PROT	T/R	LCT	SS	CONV
	R-0	RW-0	R-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 0uuu00uub on  $\overline{RIU} = 0$ .

**Bit 7: FIFO Threshold Enable 0 (FTE0).** When this bit and the FTE1 (FCR.3) bit are set, the programmable FIFO threshold feature is enabled. This bit always reads 0 for compatibility.

**Bit 6: Force Inverse Parity (FIP).** When this bit is configured to 0, the correct parity is transmitted with each character, and receive characters are checked for the correct parity. When FIP = 1, an inverse parity bit is transmitted with each character and correctly received characters are NAK'd.

**Bit 5: Reserved.** This bit must be left 0. Setting this bit to 1 causes improper device operation.

**Bit 4: Protocol Select (PROT).** This bit is set to 1 by software to select the asynchronous T = 1 protocol and is cleared to 0 to select the T = 0 protocol.

**Bit 3: Transmit/Receive (T/R).** This bit should be set by software to operate the UART in transmit mode. When this bit is changed from 0 to 1 (UART changed from receive to transmit mode), hardware sets the USR.RBF/TBE bit, indicating an empty transmit buffer. The T/R bit is automatically cleared to 0 following successful transmission if UCR1.LCT is configured to 1 prior to the transmission. This bit cannot be written to when  $\overline{RIU} = 0$  (holding in reset).

**Bit 2: Last Character to Transmit (LCT).** This bit is optionally set by software prior to writing the last character to be transmitted to the UART transmit register (UTR). If LCT is set to 1 prior to writing to UTR, hardware resets the LCT, T/R, and TBE/RBF bits following a successful transmission. Setting this bit to 1 allows automatic change to the reception mode after the last character is sent. This bit can be set during and before the transmission. This bit cannot be written to when  $\overline{RIU} = 0$  (holding in reset).

**Bit 1: Software Convention Setting (SS).** This bit should be set by software prior to ATR to allow automatic convention detection. Hardware automatically resets the SS bit at 10.5 ETU after the detection of the start bit of the first character of the ATR.

**Bit 0: Convention (CONV).** This bit defines the character decoding convention of the ISO UART. If CONV = 1, the convention is direct. If CONV = 0, the convention is inverted. If automatic convention detection is enabled ( $\overline{AUTO C} = 0$ ), hardware detects the character convention and configures the CONV bit appropriately at 10.5 ETU. Otherwise ( $\overline{AUTO C} = 1$ ), software must configure the CONV bit.

# Multiprotocol Dual Smart Card Interface

## Power Control Register (PCR)

	7	6	5	4	3	2	1	0
Address 07h	—	—	C8	C4	1V8	RSTIN	3V/5V	START
	R-0	R-0	RW-1	RW-1	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 0011uuuub on  $\overline{RIU} = 0$ .

**Note:** The AUX card interface does not have register PCR. C4 and C8 are external ports that are internally pulled up ( $10k\Omega$  to  $V_{CCx}$ ), writing a 1 to C4, C8 configures the weak pullup. Reads are made of the pin state to a different physical bit. Writing a 0 to C4, C8 configures the pulldown. C4 and C8 bits can be written irrespective of the state of the T/R bit.

### Bits 7 and 6: Reserved.

**Bit 5: Contact 8 (C8).** Writes to this register bit are output on the C8 pin of the card interface. Reads of this register bit reflect the value on the C8 pin.

**Bit 4: Contact 4 (C4).** Writes to this register bit are output on the C4 pin of the card interface. Reads of this register bit reflect the value on the C4 pin.

**Bit 3: 1.8V Card Select (1V8).** If this bit is set to 1, the  $V_{CCx}$  supplied to the card interface is 1.8V. This bit overrides the 3V/5V bit.

**Bit 2: Reset Bit (RSTIN).** When a card interface is activated, the RSTx pin is driven according to the value contained in this register bit.

**Bit 1: 3V/5V Card Select (3V/5V).** This bit determines the  $V_{CCx}$  level for the card interface. When this bit is set to 1,  $V_{CCx}$  is defined as 3V. When this bit is cleared to 0,  $V_{CCx}$  is defined as 5V. When the 1V8 and 3V/5V bits are set to 1, priority is given to 1V8.

**Bit 0: Start (START).** This bit controls software activation/deactivation of the card interface. When this bit is written to 1, the activation sequence for the selected card is performed. When this bit is written to 0, the deactivation sequence for the selected card is performed. Hardware automatically resets the START bit for the associated card interface when emergency deactivation occurs. This bit can be written regardless of the state of the  $\overline{RIU}$  bit.

## Timeout Configuration Register (TOC)

	7	6	5	4	3	2	1	0
Address 08h	TOC7	TOC6	TOC5	TOC4	TOC3	TOC2	TOC1	TOC0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 00000000b on  $\overline{RIU} = 0$ .

**Bits 7 to 0: Timeout Counter Configuration Register Bits (TOC7 to TOC0).** These register bits determine the counting configuration for the three timeout counter registers. The available configurations are detailed in

the *Timeout Counter Operation* section. These registers can be written when  $\overline{RIU} = 1$  before activation and cannot be written to when  $\overline{RIU} = 0$ .

# Multiprotocol Dual Smart Card Interface

## Timeout Counter Register 1 (TOR1)

	7	6	5	4	3	2	1	0
Address 09h	TOL7	TOL6	TOL5	TOL4	TOL3	TOL2	TOL1	TOL0
	W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is unchanged on  $\overline{RIU} = 0$ .

**Bits 7 to 0: Timeout Counter Register 1 Bits (TOL7 to TOL0).** This register can be configured to operate as an 8-bit counter or as the lowest 8 bits of a 24-bit counter. TOR1, TOR2, and TOR3 are concatenated to form a 24-bit ETU counter or a pair of independent 16- and 8-bit

counters. These counters are only used when a card is supplied an active clock. See the *Timeout Counter Operation* section for details on configurable modes.

## Timeout Counter Register 2 (TOR2)

	7	6	5	4	3	2	1	0
Address 0Ah	TOL15	TOL14	TOL13	TOL12	TOL11	TOL10	TOL9	TOL8
	W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is unchanged on  $\overline{RIU} = 0$ .

**Bits 7 to 0: Timeout Counter Register 2 Bits (TOL15 to TOL8).** This register can be configured to operate as the lower 8 bits of a 16-bit counter or as the middle 8

bits of a 24-bit counter. See the *Timeout Counter Operation* section for details on configurable modes.

## Timeout Counter Register 3 (TOR3)

	7	6	5	4	3	2	1	0
Address 0Bh	TOL23	TOL22	TOL21	TOL20	TOL19	TOL18	TOL17	TOL16
	W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is unchanged on  $\overline{RIU} = 0$ .

**Bits 7 to 0: Timeout Counter Register 3 Bits (TOL23 to TOL16).** This register can be configured to operate as the high 8 bits of a 16-bit counter or as the high 8

bits of a 24-bit counter. See the *Timeout Counter Operation* section for details on configurable modes.

# Multiprotocol Dual Smart Card Interface

## Mixed Status Register (MSR)

Address 0Ch	7	6	5	4	3	2	1	0
	CLKSW	FE	BGT	CRED	PRB	PRA	INTAUX	TBE/RBF
	R-0	R-1	R-0	R-1	R-0	R-0	R-0	R-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to  $u1u1uuu0b$  on  $\overline{RIU} = 0$ .

**Bit 7: Clock Switch (CLKSW).** This status bit indicates the clock ( $f_{XTAL} / n$  or  $f_{INT} / 2$ ) being sourced by the selected card interface and thus may be used to determine when a requested clock switch has occurred properly. When CLKSW is set 1, the clock has switched from  $f_{XTAL} / n$  to  $f_{INT} / 2$ ; when CLKSW is cleared to 0, the clock has switched from  $f_{INT} / 2$  to  $f_{XTAL} / n$ .

**Bit 6: FIFO Empty Status Bit (FE).** This bit is set to 1 when the receive FIFO is empty. This bit is cleared to 0 when at least one character remains in the receive FIFO.

**Bit 5: Block Guard Time Status Bit (BGT).** This status bit is linked to an ETU counter for the currently selected card interface, and is intended for use in verifying that the block guard time is always being met. The counter restarts on every start bit and stops only if the terminal count is reached. The terminal count is dependent upon the selected protocol (16 ETU for T = 0 and 22 ETU for T = 1). This bit is cleared to 0 on every start bit.

**Bit 4: Control Ready (CRED).** This bit signals the host device that the DS8007 is ready to handle the next write operation to UTR or TOC or the next read operation of URR. When CRED = 0, the DS8007 is still working on the previous operation and cannot correctly process the new read/write request. When CRED = 1, the DS8007 is ready for the next read/write request. This “busy” bit allows the DS8007 to meet the timing constraints of high-speed host devices. The CRED bit remains low:

- 3 clock cycles after the rising edge of  $\overline{RD}$  before reading URR.
- 3 clock cycles after the rising edge of  $\overline{WR}$  (or  $\overline{CS}$ ) before writing to UTR.

- 1/PSC (min) ETU and 2/PSC (max) ETU after the rising edge of  $\overline{WR}$  (or  $\overline{CS}$ ) before writing to TOC

The CRED bit timing applies to asynchronous mode only; this bit is forced to 1 in synchronous mode.

**Bit 3: Presence Card B (PRB).** This bit is set to 1 when card B presence is detected and is cleared to 0 when card B is not present.

**Bit 2: Presence Card A (PRA).** This bit is set to 1 when card A presence is detected and is cleared to 0 when card A is not present.

**Bit 1: INTAUX Bit (INTAUX).** This bit reflects the state of the INTAUX pin. This bit is set when the INTAUX pin is high and is cleared when the INTAUX pin is low.

**Bit 0: Transmit Buffer Empty/Receive Buffer Full (TBE/RBF).** This bit signals special conditions relating to the ISO UART and associated hardware. This bit is not set when the last character is transmitted by the UART when LCT = 1.

This bit is set to 1 when:

- UCR1.T/R is changed from 0 (receive mode) to 1 (transmit mode).
- A character is transmitted by the UART.
- The receive FIFO becomes full.

This bit is cleared to 0 when:

- The ISO UART is reset by  $\overline{RIU} = 0$ .
- A character is written to the UART transmit register (UTR) in transmit mode.
- A character is read from the receive FIFO in receive mode.
- UCR1.T/R is changed from 1 (transmit mode) to 0 (receive mode).

# Multiprotocol Dual Smart Card Interface

## FIFO Control Register (FCR)

Address 0Ch	7	6	5	4	3	2	1	0
	—	PEC2	PEC1	PEC0	FTE1	FL2	FL1	FL0
	W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 0uuu0uuub on  $\overline{RI\bar{U}} = 0$ .

### Bit 7: Reserved.

**Bits 6 to 4: Parity Error Count (PEC2 to PEC0).** These bits are used only for the T = 0 protocol to determine the number of retransmission attempts that can occur in transmit mode and the number of parity errors that can occur before the PE bit is set to 1 to indicate that the parity error limit has been reached. In transmit mode, the DS8007 attempts to retransmit a character up to (PEC2–PEC0) times (when NAK'd by the card) before the PE bit is set. Retransmission attempts are automatically made at 15 ETU from the previous start bit. If PEC2–PEC0 = 000b, no retransmission attempt is made, however, the host device can manually rewrite the character to UTR (in which case, it is re-sent as early as 13.5 ETU from the previous start bit of the error character).

In receive mode, if (PEC2–PEC0 + 1) parity errors have been detected, the USR.PE bit is set to 1. For example,

if PEC2–PEC0 = 000b, only one parity error needs to be detected for the PE bit to be set; if PEC2–PEC0 = 111b, 8 parity errors must be detected, etc. If a character is correctly received before the allowed parity error count is reached, the parity counter is reset. For the T = 1 protocol, the parity counter is not used. The PE bit is set whenever a parity error is detected for a received character.

**Bit 3: FIFO Threshold Enable 1 (FTE1).** When this bit and the FTE0 (UCR1.7) bit are set, the programmable FIFO threshold feature is enabled. This bit always reads 0 for compatibility.

**Bits 2 to 0: FIFO Length (FL2 to FL0).** These bits determine the depth of the receive FIFO. The receive FIFO has depth equal to (FL2–FL0) + 1 (e.g., FIFO depth = 2 if FL2–FL0 = 001b).

## UART Receive Register (URR)/UART Transmit Register (UTR)

Address 0Dh	7	6	5	4	3	2	1	0
	UR7/UT7	UR6/UT6	UR5/UT5	UR4/UT4	UR3/UT3	UR2/UT2	UR1/UT1	UR0/UT0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = unrestricted read, W = unrestricted write, -n = value after reset. This register is reset to 00000000b on  $\overline{RI\bar{U}} = 0$ .

**Bits 7 to 0: UART Receive Register (Read Operations)/UART Transmit Register (Write Operations) (UR7/UT7 to UR0/UT0).** This register is used both as the UART transmit and receive buffer by the host microcontroller. Received characters are always read by the host microcontroller in direct convention, meaning that if the CONV bit is 0, then characters received using inverse convention are automatically translated by the hardware. When the receive FIFO is enabled, reads of URR always access the oldest available received data. For the synchronous mode of operation, the LSb (URR.0) reflects the state of the selected card I/Ox line.

Writes by the host microcontroller to this register transmit characters to the selected card. The host microcontroller should write data to UTR in direct convention

(inverse convention encoding is handled by the hardware). The UTR register cannot be loaded during transmission. The transmission:

- Starts at the end of the write operation (rising edge of  $\overline{WR}$ ) if the previous character has been transmitted and the extra guard time has been satisfied.
- Starts at the end of the extra guard time if that guard time has not been satisfied.
- Does not start if the transmission of the previous character is not completed (e.g., during retransmission attempts or if a transmit parity error occurs).

For the synchronous mode of operation, only the LSb (UTR.0) of the loaded data is transferred to the I/Ox pin for the selected card.

# Multiprotocol Dual Smart Card Interface

## UART Status Register (USR)

Address 0Eh	7	6	5	4	3	2	1	0
	TO3	TO2	TO1	EA	PE	OVR	FER	TBE/RBF
	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

R = unrestricted read, W = unrestricted write, -n = value after reset. All register bits are reset to 00000000b on  $\overline{RTU} = 0$ .

**Note:** If any of the bits TO3, TO2, TO1, EA, PE, OVR, or FER are set, then a USR read operation clears the bit, causing an interrupt less than 2 $\mu$ s after the rising edge of the  $\overline{RD}$  strobe. PE and FER can be set by the same reception.

**Bits 7 to 5: Timeout Counter 3/2/1 Status (TO3 to TO1).** These bits are set to 1 whenever their respective timeout counter reaches its terminal count. Any of these bits causes the  $\overline{INT}$  pin to be asserted.

**Bit 4: Early Answer Detected (EA).** This bit is set to 1 if a start bit is detected on the I/O line during the ATR between clock cycles 200–368 when the RSTx pin is low, and during the first 368 clock cycles after the RSTx pin is high. When the EA bit becomes set,  $\overline{INT}$  is asserted. If the EA bit is set for a card during ATR, this bit is cleared when switched to another card. During the early answer detection period, a 46-clock-cycles sampling period should be used to detect the start bit; there is an undetected period of 32 clock cycles at the end for both cases (between clock cycles 200–368 when the RSTx pin is low, and the first 368 clock cycles after the RSTx pin is high).

**Bit 3: Parity Error (PE).** This status bit indicates when the transmit or receive parity error count has been exceeded. For protocol T = 0, the PEC2–PEC0 bits define the allowable number of transmit or receive parity errors. For protocol T = 1, any parity error results in

the setting of the PE bit. When the PE bit is set,  $\overline{INT}$  is asserted. For protocol T = 0, characters received with the incorrect parity are not stored in the receive FIFO. For protocol T = 1, received characters with parity errors are stored to the receive FIFO regardless of the parity bit. The PE bit is set at 10.5 ETU in reception mode and at 11.5 ETU in transmit mode for T = 0 and T = 1 (PE bit is not applicable for transmit for T = 1).

**Bit 2: Overrun FIFO (OVR).** This status bit is set to 1 if the UART receives a new character when the receive FIFO is full. When a FIFO overrun condition occurs, the new character received is lost and the previous FIFO content remains undisturbed. When the OVR status bit is set,  $\overline{INT}$  is asserted. The OVR bit is set at 10.5 ETU in receive mode for T = 0 and T = 1.

**Bit 1: Framing Error (FER).** This status bit is set to 1 if the I/O line is not in the high state at time = 10.25 ETU after the start bit. The FER bit is set to 10.5 ETU in receive mode for T = 0 and T = 1.

**Bit 0: Transmit Buffer Empty/Receive Buffer Full (TBE/RBF).** This is a duplicate of the same status bit contained in the Mixed Status Register (MSR).

# Multiprotocol Dual Smart Card Interface

## Hardware Status Register (HSR)

DS8007

Address 0Fh	7	6	5	4	3	2	1	0
	—	PRTL B	PRTL A	SUPL	PRL B	PRL A	INTAUXL	PTL
	R-0	R-0	R-0	R-1	R-0	R-0	R-0	R-0

R = unrestricted read, W = unrestricted write, -n = value after reset, x = always reflects state of external device pin. This register is reset to 0uuuxxxub on  $\overline{RTU} = 0$ .

**Note:** A minimum of 2 $\mu$ s is needed between successive reads of the HSR to allow for hardware updates. In addition, a minimum of 2 $\mu$ s is needed between reads of the HSR and activation of card A, card B, or the AUX card.

**Bit 7: Reserved.**

**Bit 6: Protection Card Interface B Status Bit (PRTL B).** This bit is set to 1 when a fault has been detected on card reader interface B. A fault is defined as detection of a short-circuit condition on either the RSTB or VCCB pin as given by DC specs I<sub>RST</sub>(SD) and I<sub>CC</sub>(SD). The  $\overline{INT}$  signal is asserted at logic 0 (active) while this bit is set. This bit returns to 0 after any HSR read, unless the condition persists.

**Bit 5: Protection Card Interface A Status Bit (PRTL A).** This bit is set to a 1 when a fault has been detected on card reader interface A. A fault is defined as detection of a short-circuit condition on either the RSTA or VCCA pin as given by DC specs I<sub>RST</sub>(SD) and I<sub>CC</sub>(SD). The  $\overline{INT}$  signal is asserted at logic 0 (active) while this bit is set. This bit returns to 0 after any HSR read, unless the condition persists.

**Bit 4: Supervisor Latch (SUPL).** This bit is set to 1 when  $V_{DD} < V_{RST}$  or when a reset is caused by externally driving the DELAY pin < 1.25V. At this time the  $\overline{INT}$  signal is asserted at logic 0 (active). This bit returns to 0 only after an HSR read outside the alarm pulse.

**Bit 3: Presence Latch B (PRL B).** This bit is set to 1 when a level change has been detected on the PRESB pin of card interface B. The  $\overline{INT}$  signal is asserted at logic 0 (active) while this bit is set. This bit returns to 0 after any HSR read.

**Bit 2: Presence Latch A (PRL A).** This bit is set to 1 when a level change has been detected on the PRESA pin of card interface A. The  $\overline{INT}$  signal is asserted at logic 0 (active) while this bit is set. This bit returns to 0 after any HSR read.

**Bit 1: INTAUX Latch (INTAUXL).** This bit is set to 1 when a 0 → 1 or a 1 → 0 level change has been detected on the INTAUX pin. This bit remains set, regardless of further level changes on the INTAUX pin until cleared to 0 by any HSR read.

**Bit 0: Protection Thermal Latch (PTL).** This bit is set to 1 when excessive heating (approximately +150°C or greater) is detected. The  $\overline{INT}$  signal is asserted at logic 0 (active) while this bit is set. This bit returns to 0 after any HSR read, unless the condition persists.
