## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## FAN2001／FAN2002

1A High－Efficiency Step－Down DC－DC Converter

## Features

■ 96\％Efficiency，Synchronous Operation
■ Adjustable Output Voltage Options from 0.8 V to $\mathrm{V}_{\mathrm{IN}}$
■ 2．5V to 5．5V Input Voltage Range
－Up to 1A Output Current
－Fixed Frequency 1．3MHz PWM Operation
－High Efficiency Power Save Mode
－100\％Duty Cycle Low Dropout Operation
■ Soft Start
－Output Over－Voltage Protection
－Dynamic Output Voltage Positioning
－ $25 \mu \mathrm{~A}$ Quiescent Current
－Thermal Shutdown and Short Circuit Protection
■ Pb－Free 3x3mm 6－Lead MLP Package

## Applications

－Pocket PCs，PDAs
－Cell Phones
■ Battery－Powered Portable Devices
－Digital Cameras
－Hard Disk Drives
－Set－Top－Boxes
■ Point－of－Load Power
－Notebook Computers
－Communications Equipment

## Description

Designed for use in battery－powered applications，the FAN2001／ FAN2002 is a high－efficiency，low－noise synchronous PWM cur－ rent mode and Pulse Skip（Power Save）mode DC－DC con－ verter．It can provide up to 1A of output current over a wide input range from 2.5 V to 5.5 V ．The output voltage can be externally adjusted over a wide range of 0.8 V to 5.5 V by means of an external voltage divider．
At moderate and light loads，pulse skipping modulation is used． Dynamic voltage positioning is applied，and the output voltage is shifted $0.8 \%$ above nominal value for increased headroom dur－ ing load transients．At higher loads the system automatically switches over to current mode PWM control，operating at 1.3 MHz ．A current mode control loop with fast transient response ensures excellent line and load regulation．To achieve high effi－ ciency and ensure long battery life，the quiescent current is reduced to $25 \mu \mathrm{~A}$ in Power Save mode，and the supply current drops below $1 \mu \mathrm{~A}$ in shut－down mode．The FAN2001／FAN2002 is available in a $3 \times 3 \mathrm{~mm} 6$－lead MLP package．

## Notes:

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Absolute maximum ratings apply individually only, not in combination. Unless otherwise specified, all other voltages are referenced to AGND.
2. Junction to ambient thermal resistance, $\theta_{\mathrm{JA}}$, is a strong function of PCB material, board thickness, thickness and number of copper planes, number of via used, diameter of via used, available copper surface, and attached heat sink characteristics.
3. Using Mil Std. 883E, method 3015.7(Human Body Model) and EIA/JESD22C101-A (Charge Device Model).
4. Refer to the applications section for further details.

Figure 3. Block Diagram

## Detailed Operation Description

The FAN2001/FAN2002 is a step-down converter operating in a current-mode PFM/PWM architecture with a typical switching frequency of 1.3 MHz . At moderate to heavy loads, the converter operates in pulse-width-modulation (PWM) mode. At light loads the converter enters a power-save mode (PFM pulse skipping) to keep the efficiency high.

## PWM Mode

In PWM mode, the device operates at a fixed frequency of 1.3 MHz . At the beginning of each clock cycle, the P-channel transistor is turned on. The inductor current ramps up and is monitored via an internal circuit. The P-channel switch is turned off when the sensed current causes the PWM comparator to trip when the output voltage is in regulation or when the inductor current reaches the current limit (set internally to typically 1500 mA ). After a minimum dead time the N -channel transistor is turned on and the inductor current ramps down. As the clock cycle is completed, the N -channel switch is turned off and the next clock cycle starts.

## PFM (Power Save) Mode

As the load current decreases and the inductor current reaches negative value, the converter enters pulse-frequency-modulation (PFM) mode. The transition point for the PFM mode is given by the equation:

$$
\mathrm{I}_{\text {OUT }}=\mathrm{V}_{\text {OUT }} \times \frac{1-\left(\mathrm{V}_{\text {OUT }} / \mathrm{V}_{\text {IN }}\right)}{2 \times \mathrm{L} \times \mathrm{f}}
$$

The typical output current when the device enters PFM mode is 150 mA for input voltage of 3.6 V and output voltage of 1.2 V . In

PFM mode the device operates with a variable frequency and constant peak current, thus reducing the quiescent current to minimum. Consequently, the high efficiency is maintained at light loads. As soon as the output voltage falls below a threshold, set at $0.8 \%$ above the nominal value, the P-channel transistor is turned on and the inductor current ramps up. The Pchannel switch turns off and the N -channel turns on as the peak inductor current is reached (typical 450mA).

The N -channel transistor is turned off before the inductor current becomes negative. At this time the P-channel is switched on again starting the next pulse. The converter continues these pulses until the high threshold (typical 1.6\% above nominal value) is reached. A higher output voltage in PFM mode gives additional headroom for the voltage drop during a load transient from light to full load. The voltage overshoot during this load transient is also minimized due to active regulation during turn on of the N -channel rectifier switch. The device stays in sleep mode until the output voltage falls below the low threshold. The FAN2001/FAN2002 enters the PWM mode as soon as the output voltage can no longer be regulated in PFM with constant peak current.

## 100\% Duty Cycle Operation

As the input voltage approaches the output voltage and the duty cycle exceeds the typical 95\%, the converter turns the P-channel transistor continuously on. In this mode the output voltage is equal to the input voltage minus the voltage drop across the P channel transistor:
$\mathrm{V}_{\text {OUT }}=\mathrm{V}_{\text {IN }}-\mathrm{I}_{\text {LOAD }} \times\left(\mathrm{R}_{\text {dsON }}+\mathrm{R}_{\mathrm{L}}\right)$, where
$\mathrm{R}_{\mathrm{ds}} \mathrm{ON}=\mathrm{P}$-channel switch ON resistance
$l_{\text {LOAD }}=$ Output current
$\mathrm{R}_{\mathrm{L}}=$ Inductor DC resistance

## UVLO and Soft Start

The reference and the circuit remain reset until the $\mathrm{V}_{\text {IN }}$ crosses its UVLO threshold.

The FAN2001/FAN2002 has an internal soft-start circuit that limits the in-rush current during start-up. This prevents possible voltage drops of the input voltage and eliminates the output voltage overshoot. The soft-start is implemented as a digital circuit increasing the switch current in four steps to the P-channel current limit ( 1500 mA ). Typical start-up time for a $20 \mu \mathrm{~F}$ output capacitor and a load current of 1000 mA is $800 \mu \mathrm{~s}$.

## Short Circuit Protection

The switch peak current is limited cycle-by-cycle to a typical value of 1500 mA . In the event of an output voltage short circuit, the device operates with a frequency of 400 kHz and minimum duty cycle, therefore the average input current is typically 200mA.

## Thermal Shutdown

When the die temperature exceeds $150^{\circ} \mathrm{C}$, a reset occurs and will remain in effect until the die cools to $130^{\circ} \mathrm{C}$, at that time the circuit will be allowed to restart.

## Applications Information

## Setting the Output Voltage

The internal reference is 0.8 V (Typical). The output voltage is divided by a resistor divider, R1 and R2 to the FB pin. The output voltage is given by:

$$
\mathrm{V}_{\mathrm{OUT}}=\mathrm{V}_{\mathrm{REF}}\left(1+\frac{\mathrm{R}_{1}}{\mathrm{R}_{2}}\right)
$$

Where $R_{1}+R_{2}<800 K \Omega$.
According to this equation, and assuming desired output voltage of 1.5096 V , and given $\mathrm{R} 2=10 \mathrm{~K} \Omega$, the calculated value of R 1 is $8.87 \mathrm{~K} \Omega$. If quiescent current is a key design parameter a higher value feedback resistor can be used (e.g. R2 $=100 \mathrm{~K} \Omega$ ) and a small bypass capacitor of 10 pF is required in parallel with the upper resistor as shown in Figure 4.

Figure 4. Setting the Output Voltage

## Inductor Selection

The inductor parameters directly related to the device's performances are saturation current and dc resistance. The FAN2001/ FAN2002 operates with a typical inductor value of $3.3 \mu \mathrm{H}$. The lower the dc resistance, the higher the efficiency. For saturation current, the inductor should be rated higher than the maximum load current plus half of the inductor ripple current.

This is calculated as follows:

$$
\Delta \mathrm{I}_{\mathrm{L}}=\mathrm{V}_{\text {OUT }} \times \frac{1-\left(\mathrm{V}_{\mathrm{OUT}} / \mathrm{V}_{\mathrm{IN}}\right)}{\mathrm{L} \times \mathrm{f}}
$$

where:
$\Delta \mathrm{I}_{\mathrm{L}}=$ Inductor Ripple Current
$\mathrm{f}=$ Switching Frequency
$\mathrm{L}=$ Inductor Value
Some recommended inductors are suggested in the table below:

| Inductor Value | Vendor | Part Number |
| :---: | :---: | :---: |
| $3.3 \mu \mathrm{H}$ | Panasonic | ELL6PM3R3N |
| $3.3 \mu \mathrm{H}$ | Murata | LQS66C3R3M04 |

Table 1: Recommended Inductors

## Capacitors Selection

For best performances, a low ESR input capacitor is required. A ceramic capacitor of at least $10 \mu \mathrm{~F}$, placed as close to the $\mathrm{V}_{\mathrm{IN}}$ and AGND pins of the device is recommended. The output capacitor determines the output ripple and the transient response.

| Capacitor <br> Value | Vendor | Part Number |
| :---: | :---: | :---: |
| $10 \mu \mathrm{~F}$ | Taiyo Yuden | JMK212BJ106MG |
|  |  | JMK316BJ106KL |
|  | TDK | C2012X5ROJ106K |
|  |  | C3216X5ROJ106M |
|  | Murata | GRM32ER61C106K |

## Table 2: Recommended Capacitors

## PCB Layout Recommendations

The recommended PCB layout is shown in Figures 5 and 6. The inherently high peak currents and switching frequency of power supplies require a careful PCB layout design.

Figure 5. Recommended PCB Layout (FAN2001)

Figure 6. Recommended PCB Layout (FAN2002)

Therefore, use wide traces for high current paths and place the input capacitor, the inductor, and the output capacitor as close as possible to the integrated circuit terminals. In order to minimize voltage stress to the device resulting from ever present switching spikes, use an input bypass capacitor with low ESR Note that the peak amplitude of the switching spikes depends upon the load current; the higher the load current, the higher the switching spikes. The resistor divider that sets the output voltage should be routed away from the inductor to avoid RF coupling. The ground plane at the bottom side of the PCB acts as an electromagnetic shield to reduce EMI.

For more board layout recommendations download the application note "PCB Grounding System and FAN2001/FAN2011 High Performance DC-DC Converters" (AN-42036).
