

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# FAN5421 — Single-Cell Li-Ion Switching Charger

## Features

- Fully Integrated, High-Efficiency Charger for Single-Cell Li-Ion and Li-Polymer Battery Packs
- Faster Charging than Linear
- Charge Voltage Accuracy:  $\pm 0.5\%$  at 25°C  
 $\pm 1\%$  from 0 to 125°C
- $\pm 5\%$  Charge Current Regulation Accuracy
- 20 V Absolute Maximum Input Voltage
- 6.8 V Maximum Input Operating Voltage
- 1.5 A Maximum Charge Rate
- Charge and Mode Programmable through High-Speed I<sup>2</sup>C Interface (3.4 Mb/s) with Fast Mode Plus Compatibility
  - Fast Charge / Termination Current
  - Charger Voltage
  - Safety Timer
  - Termination Enable
- 3 MHz Synchronous Buck PWM Controller with Wide Duty Cycle Range
- Small-Footprint, 1 $\mu$ H External Inductor
- Safety Timer with Reset Control
- Low Reverse Leakage to Prevent Battery Drain to VIN

## Applications

- Cell Phones, Smart Phones, PDAs
- Digital Cameras
- Portable Media Players

## Description

The FAN5421 is a highly integrated switched-mode charger that minimizes single-cell Li-Ion charging time.

The charging parameters and operating modes are programmable through an I<sup>2</sup>C interface that operates up to 3.4 Mbps. The charger circuit switches at 3 MHz to minimize the size of external passive components.

The FAN5421 provides battery charging in three phases: conditioning, constant current, and constant voltage.

Charge termination is determined by a programmable minimum current level. A safety timer with reset control provides a safety backup for the I<sup>2</sup>C host.

The IC automatically adapts to current-limited power sources by reducing the charge current to keep the input supply above a programmed voltage (default 4.52 V).

The IC automatically restarts the charge cycle when the battery falls below an internal threshold. If the input source is removed, the IC enters a high-impedance mode with leakage from the battery to the input prevented. Charge status is reported back to the host through the I<sup>2</sup>C port. Charge current is reduced when the die temperature reaches 120°C.

The FAN5421 is available in a 1.96 x 1.87 mm, 20-bump, 0.4 mm pitch, Wafer-Level Chip-Scale Package (WLCSP).

## Pin Configuration

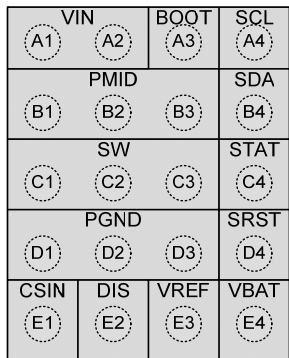

Figure 4. Top View

Figure 5. Bottom View

## Pin Definitions

Pin #	Name	Description
A1, A2	VIN	<b>Charger Input Voltage.</b> Bypass with a 1 $\mu\text{F}$ capacitor to PGND.
A3	BOOT	<b>BOOT.</b> High-side NMOS driver supply. Connect a 10nF capacitor from SW to this pin.
A4	SCL	<b>SCL.</b> I <sup>2</sup> C interface serial clock. This pin should not be left floating.
B1-B3	PMID	<b>Power Input Voltage.</b> Power input to the charger regulator, bypass point for the high-voltage input switch. Bypass with a minimum of 4.7 $\mu\text{F}$ capacitor to PGND.
B4	SDA	<b>SDA.</b> I <sup>2</sup> C interface serial data. This pin should not be left floating.
C1-C3	SW	<b>Switching Node.</b> Connect to output inductor.
C4	STAT	<b>Status.</b> Open-drain output indicating charge status. The IC pulls this pin LOW when charge is in process.
D1-D3	PGND	<b>Power GND.</b> Power return for gate drive and power transistors. The connection from this pin to the bottom of C <sub>IN2</sub> should be as short as possible.
D4	SRST	<b>Safety Reset.</b> When LOW, this pin resets the safety register to its default values. When HIGH, the safety register is reset when V <sub>BAT</sub> drops below V <sub>SHORT</sub> .
E1	CSIN	<b>Current Sense Input.</b> Connect to the sense resistor in series with the battery. The IC uses this node to sense current into the battery. Bypass this pin with a 0.1 $\mu\text{F}$ capacitor to PGND.
E2	DIS	<b>Charge Disable.</b> If this pin is HIGH, charging is disabled. When LOW, charging is controlled by the I <sup>2</sup> C registers. When this pin is HIGH, the 15-minute timer is reset; it does not affect the 32-second timer.
E3	VREF	<b>Bias Regulator Output.</b> Connect to a 1 $\mu\text{F}$ capacitor to PGND. This pin supplies the internal gate drive and power supply to the IC while charging. Up to 1 mA of current can be provided from this pin to drive the external circuits.
E4	VBAT	<b>Battery Voltage.</b> Connect to the positive (+) terminal of the battery pack. Bypass with a minimum of 10 $\mu\text{F}$ to PGND.

## Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter		Min.	Max.	Unit
$V_{IN}$	VIN Voltage	Continuous	-1.4	20.0	V
		Pulsed, 100 ms Maximum, Non-Repetitive	-2.0	20.0	V
$V_{STAT}$	STAT Voltage		-0.3	20.0	V
$V_I$	PMID		-0.3	20.0	V
	CSIN, VBAT, DISABLE		-0.3	7.0	
$V_O$	Other Pins		-0.3	6.5 <sup>(2)</sup>	V
$\frac{dV_{IN}}{dt}$	Maximum Rate of $V_{IN}$ Increase Above 10 V When IC Enabled			4	V/ $\mu$ s
ESD	Electrostatic Discharge Protection Level	Human Body Model per JESD22-A114	2.5		kV
		Charged Device Model per JESD22-C101	1.0		
$T_J$	Junction Temperature		-40	+150	°C
$T_{STG}$	Storage Temperature		-65	+150	°C
$T_L$	Lead Soldering Temperature, 10 Seconds			+260	°C

### Note:

2. Lesser of 6.5 V or  $V_{IN} + 0.3$  V.

## Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to absolute maximum ratings.

Symbol	Parameter	Min.	Max.	Unit
$V_{IN}$	Supply Voltage	4.0	6.8	V
$T_A$	Ambient Temperature	-30	+85	°C
$T_J$	Junction Temperature	-30	+120	°C

## Thermal Properties

Junction-to-ambient thermal resistance is a function of application and board layout. This data is measured with four-layer 2s2p boards in accordance to JEDEC standard JESD51. Special attention must be paid not to exceed junction temperature  $T_{J(max)}$  at a given ambient temperature,  $T_A$ .

Symbol	Parameter	Typical	Unit
$\theta_{JA}$	Junction-to-Ambient Thermal Resistance	60	°C/W
$\theta_{JB}$	Junction-to-PCB Thermal Resistance	20	°C/W

## Electrical Specifications

Unless otherwise specified: circuit of Figure 1, recommended operating temperature range for  $T_J$  and  $T_A$ ,  $V_{IN} = 5.0\text{ V}$ ,  $CE\# = HZ\_MODE = 0$ , (Charger Mode operation). SCL, SDA, and SRST = 0 or 1.8 V; typical values are for  $T_J = 25^\circ\text{C}$ .

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
<b>Power Supplies</b>						
$I_{VIN}$	VIN Current	$V_{IN} > V_{IN(min)}$ , PWM Switching		40		mA
		$V_{IN} > V_{IN(min)}$ , PWM Not Switching		300		$\mu\text{A}$
		$0^\circ\text{C} < T_J < 85^\circ\text{C}$ , $HZ\_MODE = 1$ , $V_{BAT} > V_{LOWV}$		300		$\mu\text{A}$
$I_{LKG}$	VBAT to VIN Leakage Current	$0^\circ\text{C} < T_J < 85^\circ\text{C}$ , $HZ\_MODE = 1$ , $V_{BAT} = 4.2\text{ V}$			5	$\mu\text{A}$
$I_{BAT}$	Battery Discharge Current in High-Z Mode	$0^\circ\text{C} < T_J < 85^\circ\text{C}$ , $HZ\_MODE = 1$ , $V_{BAT} = 4.2\text{ V}$			20	$\mu\text{A}$
		DISABLE = 1, $0^\circ\text{C} < T_J < 85^\circ\text{C}$ , $V_{BAT} = 4.2\text{ V}$			10	$\mu\text{A}$
<b>Charger Voltage Regulation</b>						
$V_{OREG}$	Charge Voltage Range		3.5		4.4	V
	Charge Voltage Accuracy	$T_A = 25^\circ\text{C}$ , <95% Duty Cycle	-0.5		+0.5	%
		$T_J = 0$ to $125^\circ\text{C}$ , <95% Duty Cycle	-1		+1	
<b>Charging Current Regulation</b>						
$I_{OCHRG}$	Output Charge Current Range	$V_{LOWV} < V_{BAT} < V_{OREG}$ , $V_{IN} > V_{SLP}$ , $R_{SENSE} = 68\text{ m}\Omega$ , <95% Duty Cycle	550		1550	mA
	Charge Current Accuracy Across $R_{SENSE}$	$20\text{ mV} \leq V_{RSENSE} \leq 40\text{ mV}$	92	97	102	% of Setting
		$V_{RSENSE} > 40\text{ mV}$	94	97	100	
<b>Weak Battery Detection</b>						
$V_{LOWV}$	Weak Battery Threshold Range		3.4		3.7	V
	Weak Battery Threshold Accuracy	$V_{BAT}$ Falling	-5		+5	%
	Weak Battery Deglitch Time	Rising Voltage, 2mV Overdrive		30		ms
<b>Logic Levels: DISABLE, SDA, SCL, SRST</b>

$t_{32SEC}$	32-Second Timer	32-Second Mode <sup>(6)</sup>	21.0		31.5	s
$t_{15MIN}$	15-Minute Timer	15-Minute Mode	12.0	13.5	15.0	min

### Notes:

- Negative current is current flowing from the battery to the VIN pin (discharging the battery).
- Q2 always turns on for 60 ns, then turns off if current is below  $I_{SYNC}$ .
- Guaranteed by design.
- This tolerance applies to all timers on the IC, including soft-start and deglitching timers.

## I<sup>2</sup>C Timing Specifications

Guaranteed by design.

## Circuit Description / Overview

The FAN5421 is a highly integrated synchronous buck regulator for charging that can accommodate a wide range of input sources, including USB and current-limited “wall wart” power sources. The regulator employs synchronous rectification to maintain high efficiency over a wide range of battery voltages and charge states.

When charging batteries with a current-limited input source, the switching charger’s high efficiency over a wide range of output voltages minimizes charging time.

The FAN5421 has two operating modes:

1. Charge Mode:  
Charges a single-cell Li-Ion or Li-polymer battery.
2. High-Impedance Mode:  
The charging circuits are off in this mode. Current flow from VIN to the battery or from the battery to VIN is blocked in this mode. This mode consumes very little current from VIN or the battery.

## Charge Mode

In Charge Mode, FAN5421 employs four regulation loops:

1. Charging Current: Limits the maximum charging current. This current is sensed using an external  $R_{SENSE}$  resistor.
2. Charge Voltage: The regulator is restricted from exceeding this voltage. As the internal battery voltage rises, the battery’s internal impedance and  $R_{SENSE}$  work in conjunction with the charge voltage regulation to decrease the amount of current flowing to the battery. Battery charging is completed when the voltage across  $R_{SENSE}$  drops below the  $I_{TERM}$  threshold.
3. Temperature: If the IC’s junction temperature reaches  $120^{\circ}\text{C}$ , charge current is continuously reduced until the IC’s temperature stabilizes at  $120^{\circ}\text{C}$ .
4. VIN: This loop limits the amount of drop on VIN to a programmable voltage ( $V_{SP}$ ) to accommodate “special chargers” that limit current to a lower current than might be available from a “normal” wall charger.

## Battery Charging Curve

If the battery voltage is below  $V_{SHORT}$ , a linear current source “pre-charges” the battery until  $V_{BAT}$  reaches  $V_{SHORT}$ . The PWM charging circuit is then started and the battery is charged with a constant current if sufficient input power is available. Current slew rate is limited to prevent overshoot.

The FAN5421 is designed to work with a current-limited input source at VIN. During the current regulation phase of charging, the input power source may limit the amount of current available to charge the battery and power the system. The effect of input current limit on  $I_{CHARGE}$  can be seen in Figure 21.

**Figure 20. Charge Curve When Source Current Does Not Limit  $I_{CHARGE}$**

**Figure 21. Charge Curve When Input Source Limits  $I_{CHARGE}$**

Assuming  $V_{OREG}$  is programmed to the cell’s fully charged “float” voltage, the current that the battery accepts with the PWM regulator limiting its output (sensed at  $V_{BAT}$ ) to  $V_{OREG}$  declines and the charger enters voltage regulation phase of charging. When the current declines to the programmed  $I_{TERM}$  value, the charge cycle is complete. Charge current termination can be disabled by resetting the TE bit (REG1[3]).

The charger output or “float” voltage can be programmed by the OREG bits from 3.5 V to 4.44 V in 20 mV increments, as shown in Table 3.

**Table 3. OREG Bits ( OREG[7:2] ) vs. Charger V<sub>OUT</sub> (V<sub>OREG</sub>) Float Voltage**

Decimal	Hex	V <sub>OREG</sub>	Decimal	Hex	V <sub>OREG</sub>

**Note:**

7. Default register settings are denoted by **bold typeface**.

The charging parameters in Table 4 can be programmed by the host through the I<sup>2</sup>C interface.

**Table 4. Programmable Charging Parameters**

Parameter	Name	Register
Output Voltage Regulation	V <sub>OREG</sub>	REG2[7:2]
Battery Charging Current Limit	I <sub>CHRG</sub>	REG4[6:4]
Charge Termination Limit	I <sub>TERM</sub>	REG4[2:0]
Weak Battery Voltage	V <sub>LOWV</sub>	REG1[5:4]

A new charge cycle begins when one of the following occurs:

1. The battery voltage falls below V<sub>OREG</sub> - V<sub>RCH</sub>.
2. V<sub>IN</sub> Power-On-Reset (POR) clears and the battery voltage is below the weak battery threshold (V<sub>LOWV</sub>).
3. The  $\overline{\text{CE}}$  or RESET bit is set.

**Charge Current Limit****Table 5. I<sub>CHARGE</sub> Current as a Function of the IOCHARGE Bits and R<sub>SENSE</sub> Resistor Value**

DEC	BIN	HEX	V <sub>RSENSE</sub> (mV)	I <sub>CHARGE</sub> (mA)	
				68 mΩ	100 mΩ
<b>0</b>	<b>0000</b>	<b>00</b>	<b>37.4</b>	<b>550</b>	<b>374</b>
1	0001	01	44.2	650	442
2	0010	02	51.0	750	510
3	0011	03	57.8	850	578
4	0100	04	64.6	950	646
5	0101	05	71.4	1,050	714
6	0110	06	78.2	1,150	782
7	0111	07	85.0	1,250	850
8	1000	08	91.8	1,350	918
9	1001	09	98.6	1,450	986
10	1010	0A	105.4	1,550	1,054
11	1011	0B	105.4	1,550	1,054
12	1100	0C	105.4	1,550	1,054
13	1101	0D	105.4	1,550	1,054
14	1110	0E	105.4	1,550	1,054
15	1111	0F	105.4	1,550	1,054

## Termination Current Limit

Current charge termination is enabled when TE ( REG1[3] ) = 1. Typical termination current values are given in Table 6.

**Table 6.  $I_{TERM}$  Current as a Function of the  $I_{TERM}$  Bits ( REG4[2:0] ) and  $R_{SENSE}$  Resistor Value**

ITEM	BIN	HEX	$V_{RSENSE}$ (mV)	$I_{TERM}$ (mA)	
				68 m $\Omega$	100 m $\Omega$
0	000	00	3.3	49	33
1	001	01	6.6	97	66
2	010	02	9.9	146	99
3	011	03	13.2	194	132
4	100	04	16.5	243	165
5	101	05	19.8	291	198
6	110	06	23.1	340	231
7	111	07	26.4	388	264

When the charge current falls below  $I_{TERM}$ , PWM charging stops and the STAT bits change to READY (00) for about 500ms while the IC determines whether the battery and charging source are still connected. If they are, STAT then changes to CHARGE DONE (10).

## PWM Controller in Charge Mode

The IC uses a current-mode PWM controller to regulate the output voltage and battery charge currents. A cycle-by-cycle current limit of nominally 2.3 A, sensed through Q1, is used to terminate  $t_{ON}$ . The synchronous rectifier (Q2) also has a current limit that turns off Q2 at 100 mA to prevent current flow from the battery.

## Safety Timer *see Figure 26*

At the beginning of charging process, the IC starts a 15-minute timer ( $t_{15MIN}$ ). When this timer expires, charging is terminated. Writing to any register through I<sup>2</sup>C stops the  $t_{15MIN}$  timer, which then starts a 32-second timer ( $t_{32SEC}$ ).

Setting the TMR\_RST bit ( REG0[7] ) resets the  $t_{32SEC}$  timer. If the  $t_{32SEC}$  timer expires; charging is terminated, the registers are set to default values, and charging resumes using the default values with the  $t_{15MIN}$  timer running.

Normal charging is controlled by the host with the  $t_{32SEC}$  timer running to ensure that the host is alive. Charging with the  $t_{15MIN}$  timer running is used for charging that is unattended by the host. If the 15-minute timer expires; the IC turns off the charger, sets the  $\overline{CE}$  bit, and indicates a timer fault (110) on the FAULT bits ( REG0[2:0] ). This sequence prevents overcharge if the host fails to reset the  $t_{32MIN}$  timer.

## $V_{IN}$ POR / Non-Compliant Charger Rejection

When the IC detects that  $V_{IN}$  has risen above  $V_{IN(MIN)1}$  (4.4 V), the IC applies a 110  $\Omega$  load from  $V_{IN}$  to GND. To clear the  $V_{IN}$  Power-On-Reset (POR) and begin charging,  $V_{IN}$  must remain above  $V_{IN(MIN)2}$  (4.1 V) and below  $V_{IN(OVP)}$  for  $t_{VIN\_VALID}$  (30 ms). The  $V_{IN}$  validation sequence always occurs before charging is initiated or re-initiated (for example, after a  $V_{IN}$  OVP fault or a  $V_{RCH}$  recharge initiation).

$t_{VIN\_VALID}$  ensures that unfiltered 50 / 60 Hz chargers and other non-compliant chargers are rejected.

## Boot Sequence

At  $V_{IN}$  POR, when the battery voltage is above the weak battery threshold ( $V_{LOWV}$ ), the IC operates in accordance with its I<sup>2</sup>C register settings. If  $V_{BAT} < V_{LOWV}$ , the IC sets all registers to their default values and enables the charger. This feature can revive a cell whose voltage is too low to ensure reliable host operation. Charging continues in the absence of host communication even after the battery has reached  $V_{OREG}$ , whose default value is 3.54 V, and the charger remains active until  $t_{15MIN}$  expires. Once the host processor begins writing to the IC, charging parameters are set by the host, which must continually reset the  $t_{32SEC}$  timer by writing to the TMR\_RST bit to continue charging using the programmed charging parameters. If  $t_{32SEC}$  expires, the register defaults are loaded, the FAULT bits are set to 110, STAT is pulsed HIGH, and charging continues with default charging parameters.

### Current Limited Charger: $V_{SP}$ Loop

The FAN5421 can accommodate current-limited input supplies by reducing the charging current to prevent  $V_{BUS}$  from falling below a specified limit. When a current-limited charger is supplying  $V_{IN}$ , the IC slowly increases the charging current until either:

- $I_{OCHARGE}$  is reached, or
- $V_{IN} = V_{SP}$ .

If  $V_{IN}$  collapses to  $V_{SP}$  when current is ramping up, the IC charges with an input current that keeps  $V_{IN} = V_{SP}$ . When the  $V_{SP}$  control loop is limiting the charge current, the SP bit (REG5[4]) is set.

Table 7.  $V_{SP}$  as a Function of SP Bits (REG5[2:0])

SP (REG5[2:0])			$V_{SP}$
DEC	BIN	HEX	
0	000	00	4.20
1	001	01	4.28

3	011	03	4.44
<b>4</b>	<b>100</b>	<b>04</b>	<b>4.52</b>
5	101	05	4.60
6	110	06	4.68
7	111	07	4.76

### Safety Settings

The IC contains a SAFETY register (REG6) that prevents the values in OREG (REG2[7:2]) and IOCHARGE (REG4[7:4]) from exceeding the VSAFE and ISAFE values.

After  $V_{BAT}$  rises above  $V_{SHORT}$ , the SAFETY register is loaded with its default value and may be written only before another register is written. After writing to any other register, the SAFETY register is locked until  $V_{BAT}$  falls below  $V_{SHORT}$ .

The ISAFE (REG6[6:4]) and VSAFE (REG6[3:0]) establish values that limit the maximum values of  $I_{OCHARGE}$  and  $V_{OREG}$  used by the control logic. If the host attempts to write a value higher than VSAFE or ISAFE to OREG or IOCHARGE, respectively, the VSAFE or ISAFE value appears as the OREG and IOCHARGE register value, respectively.

Table 8.  $I_{SAFE}$  ( $I_{OCHARGE}$  Limit) as a Function of ISAFE Bits (REG6[7:4])

ISAFE (REG6[7:4])			$V_{RSENSE}$ (mV)	$I_{SAFE}$ (mA)

### Thermal Regulation and Protection

When the IC's junction temperature reaches  $T_{CF}$  (about 120°C), the charger reduces its output current to prevent overheating. If the temperature continues to increase, the current is reduced to 0 when the junction is 10°C above  $T_{CF}$ . If the temperature increases beyond  $T_{SHUTDOWN}$ ; charging is suspended, the FAULT bits are set to 101, and STAT is pulsed HIGH. In Suspend Mode, all timers stop and the state of the IC's logic is preserved. Charging resumes after the die cools to about 10°C below  $T_{SHUTDOWN}$ .

### Charge Mode Input Supply Protection

#### Sleep Mode

When  $V_{IN}$  falls below  $V_{BAT} + V_{SLP}$  and  $V_{IN}$  is above  $V_{IN(MIN)}$ , the IC enters Sleep Mode to prevent the battery from draining into VIN. During Sleep Mode, reverse current is disabled by turning off Q3.

#### Input Supply Low-Voltage Detection

The IC continuously monitors  $V_{IN}$  during charging. If  $V_{IN}$  falls below  $V_{IN(MIN)}$ ; the IC terminates charging and pulses the STAT pin HIGH, sets STAT bits to 11, and sets the FAULT bits to 011.

If  $V_{IN}$  recovers above the  $V_{IN(MIN)}$  rising threshold after timer  $t_{INT}$  (about two seconds), the charging process is repeated. This function prevents the input power bus from collapsing or oscillating when the IC is connected to a suspended USB port or a low-current-capable OTG device.

#### Input Over-Voltage Detection

When  $V_{IN}$  exceeds  $V_{IN(OMP)}$ , the IC:

1. Turns off Q3,
2. Suspends charging, and
3. Sets the FAULT bits to 001, STAT bits to 11, and pulses the STAT pin.

When  $V_{IN}$  falls about 130mV below  $V_{IN(OMP)}$ , the fault is cleared and charging resumes after  $V_{IN}$  is revalidated (see *VIN POR / Non-Compliant Charger Rejection* above).

### Charge Mode Battery Detection and Protection

#### $V_{BAT}$ Over-Voltage Protection (OVP)

The OREG voltage regulation loop prevents  $V_{BAT}$  from overshooting the OREG voltage by more than 50 mV when the battery is removed. When the PWM charger is running with no battery, the TE bit is not set, and a battery is inserted that's charged to a voltage higher than  $V_{OREG}$ ; PWM pulses stop. If no further pulses occur for 30ms, the IC sets the FAULT bits to 100, STAT bits to 11, and pulses the STAT pin.

#### Battery Detection During Charging

The IC can detect presence, absence, or removal of a battery if the termination bit is set (TE=1). During normal charging; once  $V_{BAT}$  is close to  $V_{OREG}$  and the termination charge current is detected, the IC terminates charging and sets the STAT bits to 10. It then turns on a discharge current,  $I_{DETECT}$ , for  $t_{DETECT}$ . If  $V_{BAT}$  is still above  $V_{OREG} - V_{RCH}$ , the battery is present and the IC sets the FAULT bits to 000. If  $V_{BAT}$  is below  $V_{OREG} - V_{RCH}$ , the battery is absent and the IC:

1. Sets the registers to their default values,
2. Sets the FAULT bits to 111, and
3. Resumes charging with default values after delay  $t_{INT}$ .

If the battery is removed while charging with TE = 0, charging continues and  $V_{BAT}$  is regulated to  $V_{OREG}$ .

### System Operation with No Battery

The IC continues charging after VIN POR with the default parameters, regulating the V<sub>BAT</sub> line to 3.54 V until the host processor issues commands or the 15-minute timer expires. In this way, the IC can start the system without a battery.

By default, the system current is limited to 325 mA. To increase the current limit, use the following sequence.

1. Program the Safety Register.
2. Set OREG to the desired value (typically 4.18).
3. Set IOCHARGE, then reset the IOLEVEL bit.

### Battery Short-Circuit Protection

If the battery voltage is below the short-circuit threshold (V<sub>SHORT</sub>); a linear current source, I<sub>SHORT</sub>, supplies V<sub>BAT</sub> until V<sub>BAT</sub> > V<sub>SHORT</sub>.

### Charger Status / Fault Status

The STAT pin indicates the operating condition of the IC and provides a fault indicator for interrupt driven systems.

**Table 10. STAT Pin Function**

EN_STAT	Charge State	STAT Pin
0	X	OPEN
X	Normal Conditions	OPEN
1	Charging	LOW
X	Fault	128 μs Pulse, then OPEN

The FAULT bits ( R0[2:0] ) indicate the type of fault in Charge Mode, as shown in Table 11.

**Table 11. Fault Status Bits**

Fault Bit			Fault Description
B2	B1	B0	
0	0	0	Normal (No Fault)
0	0	1	V <sub>BUS</sub> OVP
0	1	0	Sleep Mode
0	1	1	Poor Input Source
1	0	0	Battery OVP
1	0	1	Thermal Shutdown
1	1	0	Timer Fault
1	1	1	No Battery

### Charge Control Bits

The following table defines the  $\overline{CE}$  and RESET bit functions.

**Table 12. Charge Control Bits**

Bit	Reg	State	Function
$\overline{CE}$	REG0[2]	0	Charging Enabled
		1	Charging Disabled
RESET	REG4[7]	1	Writing 1 resets all registers to their default values

$\overline{CE}$  is set by the FAN5421 when t<sub>15MIN</sub> timer overflows.

**Table 13. DISABLE Pin and  $\overline{CE}$  Bit Functionality**

Charging	DISABLE PIN	$\overline{CE}$ BIT: REG 01[2]
ENABLE	0	0
DISABLE	X	1
DISABLE	1	X

### VREF PIN

The VREF pin is powered from PMID and is on only when PMID > V<sub>BAT</sub> and does not drain current from the battery. The IC uses this pin for its bias supply. Its output is about 350 mV below PMID as long as PMID < 5.6 V. If V<sub>BUS</sub> / PMID rise above 5.6 V, the VREF pin remains below 5.35 V.

## I<sup>2</sup>C Interface

The FAN5421 serial interface is compatible with Standard, Fast, Fast-Plus, and High-Speed (HS) Mode I<sup>2</sup>C-Bus<sup>®</sup> specifications. The SCL line is an input. The SDA line is a bi-directional open-drain output; it can only pull down the bus when active. The SDA line only pulls LOW during data reads and when signaling ACK. All data is shifted in MSB (bit 7) first.

**Table 14. I<sup>2</sup>C Slave Address**

7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	R/W

In Hex notation, the slave address assumes a 0 LSB. The hex slave address is D4H.

## Bus Timing

As shown in Figure 27, data is normally transferred when SCL is LOW. Data is clocked in on the rising edge of SCL. Typically, data transitions shortly at or after the falling edge of SCL to allow ample time for the data to set up before the next SCL rising edge.

**Figure 27. Data Transfer Timing**

Each bus transaction begins and ends with SDA and SCL HIGH. A transaction begins with a “START” condition, which is defined as SDA transitioning from 1 to 0 with SCL HIGH, as shown in Figure 28.

**Figure 28. Start Bit**

A transaction ends with a “STOP” condition, which is defined as SDA transitioning from 0 to 1 with SCL HIGH, as shown in Figure 29.

**Figure 29. Stop Bit**

**Figure 31. Write Transaction**

**Figure 32. Read Transaction**

During a read from the FAN5421 (Figure 32), the master issues a “REPEATED START” after sending the register address and before resending the slave address. The “REPEATED START” is a 1-to-0 transition on SDA while SCL is HIGH, as shown in Figure 30.

## High-Speed (HS) Mode

The protocols for High-Speed (HS), Low-Speed (LS), and Fast-Speed (FS) Modes are identical; except the bus speed for HS mode is 3.4 MHz. HS Mode is entered when the bus master sends the HS master code 00001XXX after a START condition. The master code is sent in Fast or Fast-Plus Mode (less than 1 MHz clock) and slaves do not ACK this transmission.

The master then generates a REPEATED START condition (Figure 30) that causes all slaves on the bus to switch to HS Mode. The master then sends I<sup>2</sup>C packets, as described above, using the HS Mode clock rate and timing.

The bus remains in HS Mode until a stop bit (Figure 29) is sent by the master. While in HS Mode, packets are separated by REPEATED START conditions (Figure 30).

**Figure 30. REPEATED START Timing**

## Read and Write Transactions

The following figures outline the sequences for data read and write. Bus control is signified by the shading of the packet, defined as Master Drives Bus and Slave Drives Bus. All addresses and data are MSB first.

**Table 15. Bit Definitions for Figure 31, Figure 32**

Symbol	Definition
S	START, <i>see</i> Figure 28
A	ACK. The slave drives SDA to 0 to acknowledge the preceding packet.
$\bar{A}$	NACK. The slave sends a 1 to NACK the preceding packet.
R	REPEATED START, <i>see</i> Figure 30
P	STOP, <i>see</i> Figure 29

## Register Descriptions

FAN5421 has seven user-accessible registers, described in Table 16.

**Table 16. I<sup>2</sup>C Register Address**

Register		Address Bits							
Name	REG#	7	6	5	4	3	2	1	0
CONTROL0	0	0	0	0	0	0	0	0	0
CONTROL1	1	0	0	0	0	0	0	0	1
OREG	2	0	0	0	0	0	0	1	0

## Register Bit Definitions

The following table defines the operation of each register bit for all IC versions. Default values are in **bold** text.

Bit	Name	Value	Type	Description
<b>CONTROL0</b>		<b>Register Address: 00</b>		<b>Default Value = X1XX 0XXX</b>
7	TMR_RST SRST	1	W R	Writing a 1 resets the $t_{32SEC}$ timer. Writing a 0 has no effect. Returns the SRST pin level (1 = HIGH).
6	EN_STAT	0	R/W	Disable STAT pin function. STAT = OPEN
		1		<b>Enables STAT pin function</b>
5:4	STAT	00	R	Ready
		01		Charge in progress
		10		Charge done
		11		Fault
3	Reserved	0	R	This bit is disabled and always returns 0 when read back.
2:0	FAULT		R	Fault status bits: <i>see Table 11</i>
<b>CONTROL1</b>		<b>Register Address: 01</b>		<b>Default Value = 0011 0000 (30H)</b>
7:6	Reserved	00	R/W	These bits have no effect on the IC operation.
5:4	V <sub>LowV</sub>	00	R/W	3.4 V
		01		3.5 V
		10		3.6 V
		11		<b>3.7 V</b>
3	TE	0	R/W	<b>Disable charge current termination</b>
		1		Enable charge current termination
2	$\overline{CE}$	0	R/W	<b>Charger enabled</b>
		1		Charger disabled
1	HZ_MODE	0	R/W	<b>Not High-Impedance Mode</b>
		1		High-Impedance Mode
0	Reserved	0	R	This bit is disabled and always returns 0 when read back.
<b>OREG</b>		<b>Register Address: 02</b>		<b>Default Value = 0000 1010 (0AH)</b>
7:2	OREG		R/W	Charger output “float” voltage. Programmable from 3.5 to 4.44 V in 20 mV increments. <b>Defaults to 000010 (3.54 V): <i>see Table 3.</i></b>
1:0	Reserved	10	R	These bits are disabled and always returns 10 when read back.
