

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Linear Hall-Effect Sensor with PWM Output

Release Note: Revision bars indicate significant changes to the previous edition.

1. Introduction

The HAL 2850 is a high-precision programmable linear Hall-effect sensor.

The HAL 2850 features a temperature-compensated Hall plate with spinning current offset compensation, an A/D converter, digital signal processing, an EEPROM memory with redundancy and lock function for the calibration data, and protection devices at all pins. The internal digital signal processing is of great benefit because analog offsets, temperature shifts, and mechanical stress do not degrade digital signals.

The easy programmability allows a 2-point calibration by adjusting the output signal directly to the input signal (like mechanical angle, distance, or current). Individual adjustment of each sensor during the customer's manufacturing process is possible. With this calibration procedure, the tolerances of the sensor, the magnet, and the mechanical positioning can be compensated in the final assembly.

In addition, the temperature-compensation of the Hall IC can be fit to all common magnetic materials by programming first- and second-order temperature coefficients of the Hall sensor sensitivity. It is also possible to compensate offset drifts over temperature generated by the customer application with a first-order temperature coefficient of the sensor offset. This enables operation over the full temperature range with high accuracy.

For programming purposes, the sensor features a programming interface with a Biphase-M protocol on the DIO pin (output).

In the application mode, the sensor provides a continuous PWM signal.

The sensor is designed for hostile industrial and automotive applications ($T_J = -40\text{ °C}$ up to 170 °C). The HAL 2850 is available in the very small leaded RoHs package TO92-UT and is AECQ100 qualified.

1.1. Features

- PWM frequency programmable from 31.25 Hz up to 2 kHz
- PWM resolution between 11 bit and 16 bit depending on the PWM frequency
- The magnetic measurement range over temperature is adjustable from $\pm 24\text{ mT}$ up to $\pm 96\text{ mT}$
- Sample accurate transmission for certain periods (Each PWM period transmits a new Hall sample)
- Open-drain output with slew rate control (load independent)
- On-board diagnostics (overvoltage, output current, overtemperature, signal path overflow)
- Power-on self-test covering all memories
- 20 bit digital signal processing
- Various sensor parameter are programmable (like offset, sensitivity, temperature coefficients, etc.)
- Non-volatile memory with redundancy and lock function
- Programmable temperature compensation for sensitivity (2nd order) and offset (1st order)
- Biphase-M interface (programming mode)
- Digital readout of temperature and magnetic field information in calibration mode
- Programming and operation of multiple sensors at the same supply line
- High immunity against mechanical stress, ESD, and EMC
- Reverse voltage and ESD protection at V_{SUP} pin
- ESD protection at DIO pin
- Qualified according to AECQ-100

1.2. Major Applications

- Contactless potentiometers
- Angular measurements (e.g.; torque force, pedal position, suspension level, headlight adjustment; or valve position)
- Linear position
- Current sensing for motor control, battery management

2. Ordering Information

A Micronas device is available in a variety of delivery forms. They are distinguished by a specific ordering code:

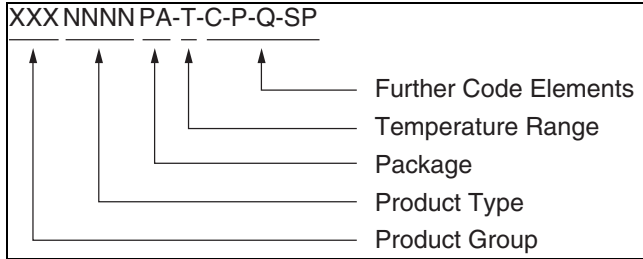

Fig. 2–1: Ordering Code Principle

For a detailed information, please refer to the brochure: “Micronas Sensors and Controllers: Ordering Codes, Packaging, Handling”.

2.1. Device-Specific Ordering Codes

HAL2850 is available in the following package and temperature variants.

Table 2–1: Available package

Package Code (PA)	Package Type
UT	TO92UT

Table 2–2: Available temperature ranges

Temperature Code (T)	Temperature Range
A	$T_J = -40\text{ °C to }+170\text{ °C}$

The relationship between ambient temperature (T_A) and junction temperature (T_J) is explained in Section 5.4. on page 29.

For available variants for Configuration (C), Packaging (P), Quantity (Q), and Special Procedure (SP) please contact Micronas.

Table 2–3: Available ordering codes and corresponding package marking

Available Ordering Codes	Package Marking
HAL2850UT-A-[C-P-Q-SP]	2850

3. Functional Description

3.1. General Function

The HAL 2850 is a monolithic integrated circuit, which provides an output signal proportional to the magnetic flux through the Hall plate.

The external magnetic field component, perpendicular to the branded side of the package, generates a Hall voltage. The Hall IC is sensitive to magnetic north and south polarity. This voltage is converted to a digital value, processed in the digital signal processing Unit (DSP) according to the settings of the EEPROM registers.

The function and the parameters for the DSP are explained in Section 3.2. on page 7.

Internal temperature compensation circuitry and the spinning current offset compensation enables operation over the full temperature range with minimal changes in accuracy and high offset stability. The circuitry also rejects offset shifts due to mechanical stress from the package.

The HAL 2850 provides two operation modes, the application mode and the programming mode.

Application Mode

The output signal is provided as continuous PWM signal.

Programming Mode

For the programming of the sensor parameters, a Biphase-M protocol is used.

The HAL 2850 provides non-volatile memory which is divided in different blocks. The first block is used for the configuration of the digital signal processing, the second one is used to configure the PWM module. The non-volatile memory employs inherent redundancy.

Fig. 3-1: HAL 2850 block diagram

3.2. Digital Signal Processing

All parameters and the values y , y_{TCI} are normalized to the interval (-1, 1) which represents the full scale magnetic range as programmed in the RANGE register.

Example for 40 mT Range

-1 equals -40 mT
 +1 equals +40 mT

For the definition of the register values, please refer to Section 3.2.2. on page 9

The digital signal processing (DSP) is the major part of the sensor and performs the signal conditioning. The parameters of the DSP are stored in the DSP CONFIG area of the EEPROM.

The device provides a digital temperature compensation. It consists of the internal temperature compensation, the customer temperature compensation, as well as an offset and sensitivity adjustment. The internal temperature compensation (factory compensation) eliminates the temperature drift of the Hall sensor itself. The customer temperature compensation is calculated after the internal temperature drift has been compensated. Thus, the customer has not to take care about the sensor's internal temperature drift.

The output value y is calculated out of the factory-compensated Hall value y_{TCI} as:

$$y = [y_{TCI} + d(TVAL)] \cdot c(TVAL)$$

Parameter d is representing the offset and c is the coefficient for sensitivity.

The current Hall value y is stored in the data register HVD immediately after it has been temperature compensated.

A new PWM period transmits the recent temperature-compensated Hall sample. A new Hall sample is transmitted by the next PWM period and samples will neither be lost nor doubly transmitted. Sample accurate transmission is available for native PWM periods (0.512 ms, 1.024 ms, 2.048 ms, 4.096 ms, 8.192 ms, 16.384 ms and 32.768 ms period).

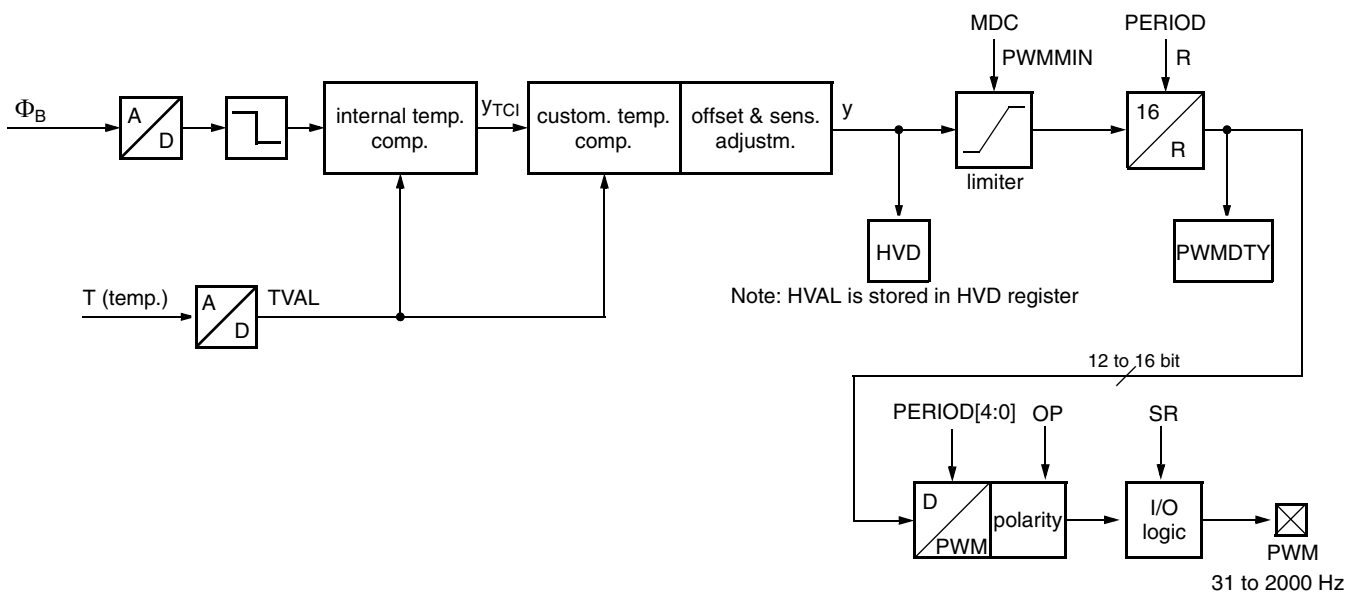

Fig. 3-2: Block diagram of digital signal path

3.2.1. Temperature Compensation

Terminology:

D0: name of the register or register value

d₀: name of the parameter

The customer programmable parameters “c” (sensitivity) and d (offset) are polynomials of the temperature. The temperature is represented by the adjusted read-out value TVAL of a built-in temperature sensor.

The update rate of the temperature value TVAL is less than 100 ms.

The sensitivity polynomial c(TVAL) is of second order in temperature:

$$c(TVAL) = c_0 + c_1 \cdot TVAL + c_2 \cdot TVAL^2$$

For the definition of the polynomial coefficients please refer to Section 3.2.2. on page 9.

The Offset polynomial d(T_{ADJ}) is linear in temperature:

$$d(TVAL) = d_0 + d_1 \cdot TVAL$$

For the definition of the polynomial coefficients, please refer to Section 3.2.2. on page 9.

For the calibration procedure of the sensor in the system environment, the two values HVAL and TADJ are provided. These values are stored in volatile registers.

HVAL

The number HVAL represents the digital output value y which is proportional to the applied magnetic field.

HVAL is a 16-bit two’s complement binary ranging from –32768 to +32767.

It is stored in the HVD register.

$$y = \frac{HVAL}{32768}$$

In case of internal overflows, the output will clamp to the maximum or minimum HVAL value. Please take care that during calibration, the output signal range does not reach the maximum/minimum value.

TVAL

The number TVAL provides the adjusted value of the built-in temperature sensor.

TVAL is a 16-bit two’s complement binary ranging from –32768 to 32767.

It is stored in the TVD register.

Note: The actual resolution of the temperature sensor is 12 bit. The 16-bit representation avoids rounding errors in the computation.

The relation between TVAL and the junction temperature T_J is

$$T_J = \alpha_0 + TVAL \cdot \alpha_1$$

Table 3–1: Relation between T_J and T_{ADJ} (typical values)

Coefficient	Value	Unit
α ₀	71.65	°C
α ₁	1 / 231.56	°C

3.2.2. DSP Configuration Registers

This section describes the function of the DSP configuration registers. For details on the EEPROM please refer to Application Note Programming of HAL 2850.

Magnetic Range: RANGE

The RANGE register defines the magnetic range of the A/D converter. The RANGE register has to be set according to the applied magnetic field range.

EEPROM. RANGE	Nominal Range
0	reserved
1	40 mT
2	60 mT
3	80 mT
4	100 mT
5	120 mT
6	140 mT
7	160 mT

For calculation of magnetic measurement range over temperature see Section 4.9. on page 20 parameter RANGE_{abs}. The minimum value has to be used in order to guarantee no clipping over temperature.

Magnetic Offset D

The D (offset) registers contain the parameters for the adder in the DSP. The added value is a first order polynomial of the temperature.

D0 Register

Table 3–2: Temperature independent coefficient

Parameter	Range	Resolution
d ₀	-0.5508 ... 0.5497	10 bit
D0	-512 ... 511	

D0 is encoded as two's complement binary.

$$d_0 = \frac{0.5508}{512} \cdot D0$$

D1 Register

Table 3–3: Linear temperature coefficient

Parameter	Range	Resolution
d ₁	-3.076 x 10 ⁻⁶ ... 3.028 x 10 ⁻⁶	7 bit
D1	-64 ... 63	

D1 is encoded as two's complement binary.

$$d_1 = \frac{0.1008}{64} \cdot D1 \cdot 3.0518 \cdot 10^{-5}$$

Magnetic Sensitivity C

The C (sensitivity) registers contain the parameters for the multiplier in the DSP. The multiplication factor is a second order polynomial of the temperature.

C0 Register

Table 3–4: Temperature independent coefficient

Parameter	Range	Resolution
c ₀	-2.0810 ... 2.2696	12 bit
C0	-2048 ... 2047	

C0 is encoded as two's complement binary:

$$c_0 = \frac{2.1758}{2048} \cdot (C0 + 89.261)$$

C1 Register

Table 3–5: Linear temperature coefficient

Parameter	Range	Resolution
c ₁	-7.955 x 10 ⁻⁶ ... 1.951 x 10 ⁻⁵	9 bit
C1	-256 ... 255	

C1 is encoded as two's complement binary.

$$c_1 = \frac{0.4509}{256} \cdot (C1 + 108.0) \cdot 3.0518 \cdot 10^{-5}$$

A failed POST is immediately setting the PWM output to the minimum duty cycle.

C2 Register

Table 3–6: Quadratic temperature coefficient

Parameter	Range	Resolution
c ₂	-1.87 x 10 ⁻¹⁰ ... 1.86 x 10 ⁻¹⁰	8 bit
C2	-128 ... 127	

C2 is encoded as two’s complement binary.

$$c_2 = \frac{0.2008}{128} \cdot C2 \cdot 9.3132 \cdot 10^{-10}$$

3.3. Power-on Self Test (POST)

The HAL 2850 features a built-in power-on self test to support in system start-up test to enhanced the system failure detection possibilities.

The power-on self test comprises the following sensor blocks:

- RAM
- ROM
- EEPROM

The power-on self test can be activated by setting certain bits in the sensors EEPROM.

Table 3–7: Power-On Self Test Modes

EEPROM. POST		Mode / Function
[1]	[0]	
0	0	POST disabled.
0	1	Memory test enabled (RAM, ROM, EEPROM).

3.3.1. Description of POST Implementation

HAL 2850 starts the internal POST as soon as the external supply voltage reaches the minimum supply voltage (V_{SUPon}). The sensor output is disabled during the POST. It is enabled after the POST has been finished (after t_{startup}).

3.3.2. RAM Test

The RAM test consists of an address test and an RAM cell test. The address test checks if each byte of the RAM can be singly accessed. The RAM cell test checks if the RAM cells are capable of holding both 0 and 1.

3.3.3. ROM Test

The ROM test consists of a checksum algorithm. The checksum is calculated by a byte by byte summation of the entire ROM. The 8-bit checksum value is stored in the ROM.

The checksum is calculated at the ROM test using the entire ROM and is then compared with the stored checksum. An error will be indicated in case that there is a difference between stored and calculated checksum.

3.3.4. EEPROM Test

The EEPROM test is similar to the ROM test. The only difference is that the checksum is calculated for the EEPROM memory and that the 8-bit checksum is stored in one register of the EEPROM.

3.4. Sensor Behavior in Case of External Errors

HAL 2850 shows the following behavior in case of external errors:

- Short of output against V_{SUP} : The sensor output is switched off (high impedance) when an over current occurs in the DIO output. It is re enabled before or while the next low pulse of the PWM signal is transmitted. Therefore the ECU must discard the first rising edge after a disturbance has occurred. The ECU has to identify destroyed PWM periods by evaluating the period time
- Break of V_{SUP} or GND line: A sensor with open-drain output and digital interface does not need a wire-break detection logic. The wire-break function is covered by the pull-up resistor on the receiver. Assuming a pull-up resistor in the receiver 100% duty-cycle (output always high) indicates a GND or V_{SUP} line break. This error can be detected one period after its occurrence
- Under or over voltage: The sensor output is switched off (high impedance) after under or over voltage has been detected by the sensor
- Over temperature detection: The sensor output is switched off (high impedance) after a too high temperature has been detected by the sensor (typ. 180°C). It is switched on again after the chip temperature has reached a normal level. A build in

hysteresis avoids oscillation of the output (typ. 25°C)

3.5. Detection of Signal Path Errors

HAL 2850 can detect the following overflows within the signal path:

- A positive overflow of the A/D converter, a positive overflow within the calculation of the low pass filter or the temperature compensation will set the PWM output to maximum duty cycle
- A negative overflow of the A/D converter, a negative overflow within the calculation of the low pass filter or the temperature compensation will set the PWM output to minimum duty cycle
- A positive or negative overflow of the A/D converter of the temperature sensor or a positive/negative overflow within the calculation of the calibrated temperature value sets the PWM output to minimum-duty-cycle

4. Specifications

4.1. Outline Dimensions

Fig. 4-1:
TO92UT-2 Plastic Transistor Standard UT package, 3 pins
Weight approximately 0.12 g

Fig. 4-2:
TO92UT-1 Plastic Transistor Standard UT package, 3 leads, spread
 Weight approximately 0.12 g

Fig. 4-3:
TO92UA/UT: Dimensions ammpack inline, not spread, standard lead length

Fig. 4-4:
TO92UA/UT: Dimensions ammpack inline, spread, standard lead length

4.2. Soldering, Welding and Assembly

Information related to solderability, welding, assembly, and second-level packaging is included in the document “Guidelines for the Assembly of Micronas Packages”. It is available on the Micronas website (<http://www.micronas.com/en/service-center/downloads>) or on the service portal (<http://service.micronas.com>).

4.3. Pin Connections and Short Descriptions

Pin No.	Pin Name	Type	Short Description
1	VSUP		Supply Voltage
2	GND		Ground
3	DIO	IN/ OUT	Digital IO PWM Output

Fig. 4–5: Pin configuration

4.4. Dimensions of Sensitive Area

0.213 mm x 0.213 mm

4.5. Positions of Sensitive Area

	TO92UT-1/-2
A4	0.4 mm
Bd	0.3 mm
D1	4.05 ±0.05 mm
H1	min. 22.0 mm, max. 24.1 mm
y	1.55 mm nominal

4.6. Absolute Maximum Ratings

Stresses beyond those listed in the “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only. Functional operation of the device at these conditions is not implied. Exposure to absolute maximum rating conditions for extended periods will affect device reliability.

This device contains circuitry to protect the inputs and outputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than absolute maximum-rated voltages to this high-impedance circuit.

All voltages listed are referenced to ground (GND).

Symbol	Parameter	Pin Name	Min.	Max.	Unit	Comment
T _J	Junction Operating Temperature	–	–40	190 ¹⁾	°C	not additive

4.6.1. Storage and Shelf Life

Information related to storage conditions of Micronas sensors is included in the document “Guidelines for the Assembly of Micronas Packages”. It gives recommendations linked to moisture sensitivity level and long-term storage.

It is available on the Micronas website (<http://www.micronas.com/en/service-center/downloads>) or on the service portal (<http://service.micronas.com>).

4.7. Recommended Operating Conditions

Functional operation of the device beyond those indicated in the “Recommended Operating Conditions/Characteristics” is not implied and may result in unpredictable behavior, reduce reliability and lifetime of the device.

All voltages listed are referenced to ground (GND).

Symbol	Parameter	Pin Name	Min.	Max.	Unit	Remarks
V _{SUP}	Supply Voltage	VSUP	4.5	17	V

4.9. Magnetic Characteristics

at $T_J = 40\text{ °C}$ to $+170\text{ °C}$, $V_{SUP} = 4.5\text{ V}$ to 17 V , $GND = 0\text{ V}$,
 at Recommended Operation Conditions if not otherwise specified in the column Conditions.
 Typical Characteristics for $T_J = 25\text{ °C}$ and $V_{SUP} = 5\text{ V}$.

Symbol	Parameter	Pin Name	Min.	Typ.	Max.	Unit	Conditions
$RANGE_{ABS}$	Absolute Magnetic Range of A/D Converter	–	60	100	110	%	% of nominal RANGE Nominal RANGE programmable from $\pm 40\text{ mT}$ up to $\pm 160\text{ mT}$
INL	Full Scale Non-Linearity	DIO	-0.25	0	0.25		% of full-scale RANGE = 1 ($\pm 40\text{ mT}$)
			-0.15	0	0.15		% of full-scale RANGE ≥ 2 ($\geq \pm 60\text{ mT}$)
ES	Sensitivity Error over Junction Temperature Range	DIO	-1	0	1	%	at $T_J = -40\text{ °C}$ to 120 °C (see Section 4.9.1.)
ES	Sensitivity Error over Junction Temperature Range	DIO	-1.5	0	1.5	%	at $T_J = 120\text{ °C}$ to 170 °C (see Section 4.9.1.)
B_{OFFSET}	Magnetic Offset	DIO	-0.4	0	0.4	mT	$B = 0\text{ mT}$, $T_A = 25\text{ °C}$ RANGE 80 mT
ΔB_{OFFSET}	Magnetic Offset Drift over Temperature Range $B_{OFFSET}(T) - B_{OFFSET}(25\text{ °C})$	DIO	-5	0	5	$\mu\text{T}/\text{°C}$	$B = 0\text{ mT}$ RANGE 80 mT

4.9.1. Definition of Sensitivity Error ES

ES is the maximum of the absolute value of the quotient of the normalized measured value¹⁾ over the normalized ideal linear²⁾ value minus 1:

$$ES = \max \left(\text{abs} \left(\frac{\text{meas}}{\text{ideal}} - 1 \right) \right) \Big|_{[T_{Jmin}, T_{Jmax}]}$$

In the example shown in Fig. 4–6 on page 21 the maximum error occurs at -10 °C:

$$ES = \frac{1.001}{0.993} - 1 = 0.8\%$$

- 1) normalized to achieve a least-squares method straight line that has a value of 1 at 25 °C
- 2) normalized to achieve a value of 1 at 25 °C

Fig. 4–6: Definition of sensitivity error (ES)

5. The PWM Module

The HAL 2850 transmits the magnetic field information by sending a PWM signal.

A pulse width modulated (PWM) signal consists of successive square wave pulses. The information is coded in the ratio between high time “ t_{high} ” and low time “ t_{low} ”.

$$duty\ cycle = \frac{t_{high}}{t_{period}}$$

Table 5–1 describes the PWM interface timing.

After reset, the output is recessive high. The transmission starts after the first valid Hall value has been calculated. In case of an overcurrent in the DIO output, the transmit transistor is switched off (high impedance). The transistor is re-enabled before transmitting a new pulse.

The first PWM period after a reset or an overcurrent condition cannot be captured due to no edge at the beginning of the transmission.

The PWM signal can be configured by the EEPROM bits PERIOD, PERIOD_ADJ (Trimming of native PWM periods), MDC (minimum/maximum duty cycle), SR (slew rate) and OP (output polarity) (see Section 5.1. on page 24).

The native PWM periods can be set by the EEPROM bit field PERIOD. Native PWM periods are 0.512 ms, 1.024 ms,..., 16.384 ms and 32.768 ms (see Table on page 24).

The EEPROM field PERIOD_ADJ can be used to trim the PWM period in small steps. This feature enables variable PWM periods in between the natural periods (see Table on page 24).

The output polarity can be configured by the flag OP in the EEPROM. According to the OP value, a PWM period starts either with a high pulse (OP = 0) or with a low pulse (OP = 1). Please note that if OP is set to 1, the output is recessive high until the output has been enabled (t_{OE} has been elapsed). After the output has been enabled, it remains low until the transition within the first period (see Fig. 5–2).

The slew rate can be configured by the bits SR in the EEPROM. See Table 5–1 for selectable slew rates.

Note: Please consider at which edge a new period starts. When OP is set to zero, a new period starts with the rising edge and the period must be captured by triggering the rising edge.

Fig. 5–1: PWM interface startup timing

Fig. 5–2: PWM interface startup timing for inverted output

Table 5–1: PWM interface timing

Symbol	Parameter	Min.	Typ.	Max.	Unit	Remark
$t_{startup}$	Startup Time ¹⁾	–	–	8 9 10 10 20 40 80	ms	Period = 0.5 ms Period = 1 ms Period = 2 ms Period = 4 ms Period = 8 ms Period = 16 ms Period = 32 ms
t_{OE}	Output Enable Time	60	–	150 ²⁾	μs	
PWM_{Jitter}	PWM Period Sample to Sample Jitter (RMS)	–	30	60	ns	Period = 0.5 ms
$DUTY_{Jitter}$	PWM Duty Cycle Sample to Sample Jitter (RMS)	–	63	125	ns	Period = 0.5, ±100 mT RANGE, B = 0 mT, including noise
t_{period}	PWM Period	see Fig. 5–1 and Fig. 5–2				PWM period is customer programmable
DUTY	PWM High Duty Cycle	t_{high} / t_{period}			%	
¹⁾ Values are valid for deactivated power-on self test. 10 ms must be added when power-on self test is active. ²⁾ 10 ms must be added when power-on self test is active.						

5.1. Programmable PWM Parameter

PWM Periods

Table 5–2: Supported native PWM periods

PWM Period	Sample Frequency	PERIOD Bit No.		
	Typ.	[4:2]	[1]	[0]
[ms]	[Hz]			
0.512	1953	0	0	0
1.024	977	0	0	1
2.048	488	0	1	1
4.096	244	1	1	1
8.192	122	2	1	1
16.384	61	3	1	1
32.768	31	4	1	1

Table 5–3: Supported intermediate PWM period

EEPROM.PERIOD	Period steps	max. Period, PERIOD_ADJ = 0				min. Period, PERIOD_ADJ = 255			
		PWM period	resolution	C ₀ for full magnetic range, MDC=0	magnetic range for C ₀ = 1, MDC=0	PWM period	resolution	C ₀ for full magnetic range, MDC=0	magnetic range for C ₀ = 1, MDC=0
[LSB]	[μs]	[ms]	[LSB]		[%]	[ms]	[LSB]		[%]
0	1	0.512	12	0.9375	93.75	0.257	11	0.4395	43.95
1	2	1.024	13	0.9688	96.88	0.514	12	0.4707	47.07
3	4	2.048	14	0.9844	98.44	1.028	13	0.4863	48.63
7	8	4.096	15	0.9922	99.22	2.056	14	0.4941	49.41
11	16	8.192	16	0.9961	99.61	4.112	15	0.4980	49.80
15	32	16.384	16	0.9961	99.61	8.224	15	0.4980	49.80
19	64	32.768	16	0.9961	99.61	16.448	15	0.4980	49.80

Note: When the period is trimmed with the PERIOD_ADJ register, then either the measurable magnetic range is reduced or the resolution is reduced.

The PWM period is faster than the sample rate when PERIOD_ADJ is greater than 0. Aliasing may occur due to double transmitted samples.

Minimum Duty Cycle

The minimum and maximum duty cycle is symmetrical to 50% duty cycle. The MDC register acts on the minimum and maximum duty cycle. The minimum and maximum duty cycle depend on the output slew rates and the PWM period (see Table 5–4).

The minimum/maximum duty cycle can be calculated with the following equations:

$$\begin{aligned} \text{PWMPER16} &= 2^{16} - (\text{PERIOD_ADJ} \times 2^7) \\ \text{PWMMIN} &= (1 + \text{MDC}) \times 2^9 \end{aligned}$$

$$\begin{aligned} \text{PWMMAX} &= \text{PWMPER16} - \text{PWMMIN} \\ \text{PWMPERIOD} &= \text{trunc}(\text{PWMPER16} / 2^{(16-R)}) \end{aligned}$$

Definition:

R:	PWM resolution in LSB (see Table)
PWMMIN:	minimum high time in LSB
PWMMAX:	maximum low time in LSB
PWMPERIOD:	PWM period in LSB
PWMPER16:	PWM period in LSB for 16 bit resolution
MDC:	EEPROM value for adjusting min./max. duty cycle
PERIOD_ADJ:	EEPROM value for adjusting the period

The measured high duty cycle (DUTY) may differ from the internal high duty cycle (DUTY_i) due of internal delays within the output logic, a difference between the rising and falling slope time, the threshold voltage of the external receiver; and other effects.

Setting the clamping levels reduces the measurable magnetic range (C0 = 1). The full magnetic range can be used in case the slope coefficient C0 is used for compressing the range of HVAL.
