Ehips<u>mall</u>

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

DEVICES

25 MHz to 3000 MHz Fractional-N PLL with Integrated VCO

Data Sheet **HMC832A**

FEATURES

RF bandwidth: 25 MHz to 3000 MHz 3.3 V supply Maximum phase detector rate: 100 MHz Ultralow phase noise −110 dBc/Hz in band (typical), f^O at 1600 MHz Fractional figure of merit (FOM): −226 dBc/Hz 24-bit step size, 3 Hz typical resolution Exact frequency mode with 0 Hz frequency error Fast frequency hopping 40-lead, 6 mm × 6 mm LFCSP package: 36 mm²

APPLICATIONS

Cellular infrastructure Microwave radios WiMax, WiFi Communications test equipment CATV equipment DDS replacement Military Tunable reference sources for spurious-free performance

GENERAL DESCRIPTION

The HMC832A is a 3.3 V, high performance, wideband, fractional-N, phase-locked loop (PLL) that features an integrated voltage controlled oscillator (VCO) with a fundamental frequency of 1500 MHz to 3000 MHz and an integrated VCO output divider (divide by 1, 2, 4, 6, … 62) that enables the HMC832A to generate continuous frequencies from 25 MHz to 3000 MHz. The integrated phase detector (PD) and Σ -Δ modulator, capable of operating at up to 100 MHz, permit wider loop bandwidths and faster frequency tuning with excellent spectral performance.

Industry leading phase noise and spurious performance, across all frequencies, enable the HMC832A to minimize blocker effects, and to improve receiver sensitivity and transmitter spectral purity. A low noise floor (−160 dBc/Hz eliminates any contribution to modulator/mixer noise floor in transmitter applications.

FUNCTIONAL BLOCK DIAGRAM

The HMC832A is footprint compatible to the HMC830 PLL with an integrated VCO. It features 3.3 V supply and innovative programmable performance technology that enables the HMC832A to tailor current consumption and corresponding noise floor performance to individual applications by selecting either a low current consumption mode or a high performance mode for improved noise floor performance.

Additional features of the HMC832A include 12 dB of RF output gain control in 1 dB steps; an output mute function to automatically mute the output during frequency changes when the device is not locked; selectable output return loss; programmable differential or single-ended outputs, with the ability to select either output in single-ended mode; a Σ - Δ modulator exact frequency mode that enables users to generate output frequencies with 0 Hz frequency error; and a register configurable 3.3 V or 1.8 V serial port interface (SPI).

SPECIFICATIONS

VPPCP, VDDLS, VCC1, VCC2, RVDD, AVDD, DVDD, VCCPD, VCCHF, VCCPS = 3.3 V minimum and maximum specified across the temperature range of −40°C to +85°C.

Data Sheet **HMC832A**

HMC832A Data Sheet

¹ Measured with 100 Ω external termination. See the Reference Input Stage section for more details.

2 Slew rate of ≥0.5 ns/V is recommended. See the Reference Input Stage section for more details. Frequency is guaranteed across process voltage and temperature from −40°C to +85°C.

 3 This maximum PD frequency can only be achieved if the minimum N value is respected. For example, in the case of fractional mode, the maximum PD frequency = f_{VCO} /20 or 100 MHz, whichever is less.

4 External 1 kΩ pull-up resistor to 1.8 V.

⁵ Limited by the 1 kΩ pull-up resistor and NMOS R_{oN}.

⁶ 10 pF load capacitor.

⁷ 10 pF load capacitor, 1 kΩ pull-up resistor. In general, open-drain mode can support higher frequencies at the expense of maximum V_{oL}. The maximum frequency for a given pull-up resistor and load capacitor is approximately 1/(10 × R_{PULL-UP} × C_{LOAD}). For example, a 10 pF load capacitor and 1 kΩ pull-up resistor can support up to 10 MHz, where V_{oL} maximum = V_{DD} × R_{ON}/(1 kΩ + R_{ON}) ≈ 164 mV. With a 500 Ω pull-up resistance and a 10 pF load, a 20 MHz maximum frequency is possible, and the maximum $V_{\text{O}I}$ increases to 300 mV.

⁸ 1 kΩ pull-up resistor.

 9 The minimum resistive load to ground in CMOS mode is 1 kΩ.

¹⁰ The LD/SDO pin does not have short-circuit protection. The maximum current of 7.2 mA must not be exceeded under any condition.

 11 C_{LOAD} in pF. C_{LOAD} maximum = 20 pF.

¹² For detailed current consumption information, refer to Figure 33 and Figure 36.

¹³ Gain setting = 6 (VCO_REG 0x07[3:0] = 6d) in high performance mode (VCO_REG 0x03[1:0] = 3d).

¹⁴ Pushing refers to a change in VCO frequency due to a change in the power supply voltage.

ABSOLUTE MAXIMUM RATINGS

Table 4.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

RECOMMENDED OPERATING CONDITIONS

Table 5. Recommended Operating Conditions

¹ Using the layout design guidelines set out in the Qualification Test Report is strongly recommended.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The HMC832A PLL with integrated VCO is composed of two subsystems: PLL subsystem and VCO subsystem, as shown in Figure 38.

PLL SUBSYSTEM OVERVIEW

The PLL subsystem divides down the VCO output to the desired comparison frequency via the N-divider (integer value set in Register 0x03, fractional value set in Register 0x04), compares the divided VCO signal to the divided reference signal (reference divider set in Register 0x02) in the phase detector (PD), and drives the VCO tuning voltage via the charge pump (CP) (configured in Register 0x09) to the VCO subsystem. Some of the additional PLL subsystem functions include

- Σ- $Δ$ configuration (Register 0x06).
- Exact frequency mode (configured in Register 0x0C, Register 0x03, and Register 0x04).
- Lock detect (LD) configuration (use Register 0x07 to configure LD and Register 0x0F to configure the LD/SDO output pin).
- External CEN pin used for the hardware PLL enable pin. The CEN pin does not affect the VCO subsystem.

Typically, only writes to the divider registers (integer part uses Register 0x03, fractional part uses Register 0x04) of the PLL subsystem are required for HMC832A output frequency changes.

The divider registers of the PLL subsystem (Register 0x03 and Register 0x04) set the fundamental frequency (1500 MHz to 3000 MHz) of the VCO subsystem. Output frequencies ranging from 25 MHz to 1500 MHz are generated by tuning to the appropriate fundamental VCO frequency (1500 MHz to 3000 MHz) by programming the N divider (Register 0x03 and Register 0x04) and programming the output divider (divide by 1 to 62, in VCO_REG 0x02) in the VCO subsystem.

For detailed frequency tuning information and an example, see the Frequency Tuning section.

VCO SUBSYSTEM OVERVIEW

The VCO subsystem consists of a capacitor switched step tuned VCO and an output stage. In typical operation, the VCO subsystem is programmed with the appropriate capacitor switch setting that is executed automatically by the PLL subsystem autocalibration state machine when autocalibration is enabled (Register $0x0A[11] = 0$; see the VCO Calibration section for more information). The VCO tunes to the fundamental frequency (1500 MHz to 3000 MHz), and is locked by the CP output from the PLL subsystem. The VCO subsystem controls the output stage of the HMC832A, enabling configuration of

- User defined performance settings (see the Programmable Performance Technology section) that are configured via VCO_REG 0x03[1:0].
- VCO output divider settings that are configured in VCO_REG 0x02 (divide by 2 to 62 to generate frequencies from 25 MHz to 1500 MHz, or divide by 1 to generate fundamental frequencies between 1500 MHz and 3000 MHz).
- Output gain settings (VCO_REG 0x07[3:0]).
- Output return loss setting (VCO_REG 0x03[5]). See Figure 26 for more information.
- Single-ended or differential output operation (VCO_REG 0x03[3:2]).
- Mute (VCO_REG 0x03[8:7]).

SPI CONFIGURATION OF PLL AND VCO SUBSYSTEMS

The two subsystems (PLL subsystem and VCO subsystem) have their own register maps as shown in the PLL Register Map and VCO Subsystem Register Map sections. Typically, writes to both register maps are required for initialization and frequency tuning operations.

As shown in Figure 38, the PLL subsystem is connected directly to the SPI of the HMC832A, whereas the VCO subsystem is connected indirectly through the PLL subsystem to the

HMC832A SPI. As a result, writes to the PLL register map are written directly and immediately, whereas the writes to the VCO subsystem register map are written to the PLL Register 0x05 and forwarded via the internal VCO SPI (VSPI) to the VCO subsystem. This is a form of indirect addressing.

VCO subsystem registers are write only and cannot be read. For more information, see the VCO Serial Port Interface (VSPI) section.

VCO Serial Port Interface (VSPI)

The HMC832A communicates with the internal VCO subsystem via an internal 16-bit VCO SPI. The internal serial port controls the step tuned VCO and other VCO subsystem functions.

The internal VSPI runs at the rate of the autocalibration finite state machine (FSM) clock, t_{FSM} (see the VCO Autocalibration section), where the FSM clock frequency cannot be greater than 50 MHz. The VSPI clock rate is set by Register 0x0A[14:13].

Writes to the control registers of the VCO are handled indirectly via writes to Register 0x05 of the HMC832A. A write to Register 0x05 causes the internal PLL subsystem to forward the packet, MSB first, across its internal serial link to the VCO subsystem, where it is interpreted.

VSPI Use of Register 0x05

The packet data written into Register 0x05 is subparsed by logic at the VCO subsystem into the following three fields:

Field 1—Bits[2:0]: 3-bit VCO_ID, target subsystem address = 000b.

Field 2—Bits[6:3]: 4-bit VCO_REGADDR, the internal register address inside the VCO subsystem.

Field 3—Bits[15:7]: 9-bit VCO_DATA, the data field to write to the VCO register.

For example, to write 0 1111 1110 into Register 2 of the VCO subsystem (VCO_ID = 000b), and set the VCO output divider to divide by 62, the following must be written to Register $0x05 =$ 0 1111 1110b, 0010b, 000b or, equivalently, Register 0x05 = 0x7F10.

During autocalibration, the autocalibration controller writes into the VCO register address specified by the VCO_ID and VCO_REGADDR, as stored in Register 0x05[2:0] and

Register 0x05[6:3], respectively. Autocalibration requires that these values be zero (Register $0x05[6:0] = 0$); otherwise, when they are not zero (Register 0x05[6:0] \neq 0), autocalibration does not function.

To ensure that the autocalibration functions, it is critical to write Register $0x05[6:0] = 0$ after the last VCO subsystem write but prior to an output frequency change that is triggered by a write to either Register 0x03 or Register 0x04.

However, it is impossible to write only Register $0x05[6:0] = 0$ (VCO_ID and VCO_REGADDR) without writing VCO_DATA (Register 0x05[15:7]). Therefore, to ensure that VCO_DATA (Register 0x05[15:7]) is not changed, it is required to read the switch settings provided in Register 0x10[7:0], and then rewrite them to Register 0x05[15:7], as follows:

- 1. Read Register 0x10.
- 2. Write to Register $0x05[15:14]$ = Register $0x10[7:6]$; Register $0x05[13] = 1$ (reserved bit); Register $0x05[12:8] =$ Register $0x10[4:0]$; and Register $0x05[7:0] = 0$.

Changing the VCO subsystem configuration (see the VCO Subsystem Register Map section) without following this procedure results in a failure to lock to the desired frequency.

For applications not using the read functionality of the HMC832A SPI, in which Register 0x10 cannot be read, it is possible to write Register $0x05 = 0x0$ to set Register $0x05[6:0] =$ 0, which also sets the VCO subband setting equal to zero (Register $0x05[15:7] = 0$), effectively programming incorrect VCO subband settings and causing the HMC832A to lose lock. This procedure is then immediately followed by a write to

- Register 0x03, if in integer mode
- Register 0x04, if in fractional mode

This write effectively retriggers the autocalibration state machine, forcing the HMC832A to relock whether in integer or fractional mode.

This procedure causes the HMC832A to lose lock and relock after every VCO subsystem change. Typical output frequency and lock time is shown in Figure 27 and Figure 30, respectively. Lock time is typically in the order of 100 μs for a phase settling of 10°, and is dependent on loop filter design (loop filter bandwidth and loop filter phase margin).

VCO SUBSYSTEM

Figure 40. Simplified Step Tuned VCO

The HMC832A contains a VCO subsystem that can be configured to operate in

- Fundamental frequency (fo) mode (1500 MHz to 3000 MHz).
- Divide by N mode, where $N = 2, 4, 6, 8 ... 58, 60, 62$ (25 MHz to 1500 MHz).

All modes are VCO register programmable, as shown in Figure 39. One loop filter design can be used for the entire frequency of operation of the HMC832A.

VCO Calibration

VCO Autocalibration

The HMC832A uses a step tuned type VCO. A simplified step tuned VCO is shown in Figure 40. A step tuned VCO is a VCO with a digitally selectable capacitor bank allowing the nominal center frequency of the VCO to be adjusted or stepped by switching in and out of the VCO tank capacitors. More than one capacitor can be switched in at a time.

A step tuned VCO allows the user to center the VCO on the required output frequency while keeping the varactor tuning voltage optimized near the midvoltage tuning point of the

HMC832A charge pump. This enables the PLL charge pump to tune the VCO over the full range of operation with both a low tuning voltage and a low tuning sensitivity (k_{VCO}) .

The VCO switches are normally controlled automatically by the HMC832A using the autocalibration feature. The autocalibration feature is implemented in the internal state machine. It manages the selection of the VCO subband (capacitor selection) when a new frequency is programmed. The VCO switches can also be controlled directly via Register 0x05 for testing or for special purpose operations. Other control bits specific to the VCO are also sent via Register 0x05.

To use a step tuned VCO in a closed loop, the VCO must be calibrated such that the HMC832A knows which switch position on the VCO is optimum for the desired output frequency. The HMC832A supports autocalibration of the step tuned VCO. The autocalibration fixes the VCO tuning voltage at the optimum midpoint of the charge pump output, then measures the free running VCO frequency while searching for the setting, which results in the free running output frequency that is closest to the desired phase-locked frequency. This procedure results in a phase-locked oscillator that locks over a narrow voltage range on the varactor. A typical tuning curve for a step tuned VCO is shown in Figure 41. Note that the tuning voltage stays in a narrow range over a wide range of output frequencies.

Figure 41. Typical VCO Tuning Voltage After Calibration

The calibration is normally run automatically, once for every change of frequency. This autocalibration ensures optimum selection of VCO switch settings vs. time and temperature. The user does not normally need to be concerned about which switch setting is used for a given frequency because this is handled by the autocalibration routine.

The accuracy required in the calibration affects the amount of time required to tune the VCO. The calibration routine searches for the best step setting that locks the VCO at the current programmed frequency and ensures that the VCO stays locked and performs well over its full temperature range without additional calibration, regardless of the temperature at which the VCO was calibrated.

Autocalibration can also be disabled, thereby allowing manual VCO tuning. Refer to the Manual VCO Calibration for Fast Frequency Hopping section for more information about manual tuning.

Autocalibration Using Register 0x05

Autocalibration transfers switch control data to the VCO subsystem via Register 0x05. The address of the VCO subsystem in Register 0x05 is not altered by the autocalibration routine. The address and ID of the VCO subsystem in Register 0x05 must be set to the correct value before autocalibration is executed. For more information, see the VCO Serial Port Interface (VSPI) section.

Automatic Relock on Lock Detect Failure

It is possible, by setting Register 0x07[13], to have the VCO subsystem automatically rerun the calibration routine and relock itself if the lock detect indicates an unlocked condition for any reason. With this option, the system attempts to relock only once.

VCO Autocalibration on Frequency Change

Assuming Register $0x0A[11] = 0$, the VCO calibration starts automatically whenever a frequency change is requested. To rerun the autocalibration routine for any reason at the same frequency, rewrite the frequency change with the same value, and the autocalibration routine executes again without changing the final frequency.

VCO Autocalibration Time and Accuracy

The VCO frequency is counted for t_{MMT} , the period of a single autocalibration measurement cycle.

$$
t_{MMT} = t_{XTAL} \times R \times 2^n \tag{1}
$$

where:

 t_{XTAL} is the period of the external reference (crystal) oscillator. R is the reference path division ratio currently in use, set in Register 0x02.

 n is set by Register 0x0A[2:0] and results in measurement periods that are multiples of the PD period, $t_{\text{XTAL}} \times R$.

The VCO autocalibration counter, on average, expects to register N counts, rounded down (floor) to the nearest integer, for every PD cycle.

N is the ratio of the target VCO frequency, f_{VCO} , to the frequency of the PD, f_{PD} , where N can be any rational number supported by the N divider.

N is set by the integer and fractional register contents using Equation 2.

$$
N = N_{INT} + N_{FRAC}/2^{24}
$$
 (2)

where:

 N_{INT} is the integer set in Register 0x03.

 N_{FRAC} is the fractional part set in Register 0x04.

13110-046

3110-046

The autocalibration state machine and the data transfers to the internal VCO VSPI run at the rate of the FSM clock, t_{FSM} , where the FSM clock frequency cannot be greater than 50 MHz.

$$
t_{FSM} = t_{XTAL} \times 2^m \tag{3}
$$

where m is 0, 2, 4, or 5 as determined by Register 0x0A[14:13].

The expected number of VCO counts, V, is given by

$$
V = floor (N \times 2^n) \tag{4}
$$

The nominal VCO frequency measured, f_{VCOM} , is given by

$$
f_{VCOM} = V \times f_{XTAL}/(2^n \times R)
$$
 (5)

where the worst case measurement error, f_{ERR} , is

$$
f_{ERR} \approx \pm f_{PD}/2^{n+1} \tag{6}
$$

A 5-bit step tuned VCO, for example, nominally requires five measurements for calibration or in the worst case, six measurements, and therefore, seven VSPI data transfers of 20 clock cycles each. The measurement has a programmable number of wait states, k, of 128 FSM cycles defined by Register $0x0A[7:6] = k$. Total calibration time, worst case, is given by

$$
t_{CAL} = k128 \ t_{FSM} + 6t_{PD} \ 2^n + 7 \times 20 \ t_{FSM} \tag{7}
$$

or equivalently

$$
t_{CAL} = t_{XTAL} (6R \times 2^n + (140 + (k \times 128)) \times 2^m)
$$
 (8)

For guaranteed hold of lock, across temperature extremes, the resolution must be better than $1/8th$ of the frequency step caused by a VCO subband switch change. Better resolution settings show no improvement.

VCO Autocalibration Example

The VCO subsystem must satisfy the maximum f_{PD} limited by the two following conditions:

$$
N \ge 16 \, (f_{INT}), N \ge 20.0 \, (f_{FRAC})
$$

where:

 $N = f_{\text{VCO}}/f_{\text{PD}}$. $f_{\text{PD}} \leq 100$ MHz. $f_{\rm INT}$ is integer mode.

 f_{FRAC} is fractional-N mode. The minimum N values changes depending on the operating mode.

For example, if the VCO subsystem output frequency is to operate at 2.01 GHz and the crystal frequency is $f_{\text{XTAL}} = 50 \text{ MHz}$, $R = 1$, and $m = 0$ (see Figure 42), then $t_{FSM} = 20$ ns (50 MHz).

When using autocalibration, the maximum autocalibration FSM clock cannot exceed 50 MHz (see Register 0x0A[14:13]). The FSM clock does not affect the accuracy of the measurement; it only affects the time to produce the result. This same clock clocks the 16-bit VCO serial port.

If the time to change frequencies is not a concern, the calibration time for maximum accuracy can be set and, therefore, the measurement resolution is of no concern.

Using an input crystal of 50 MHz ($R = 1$ and $f_{\text{PD}} = 50$ MHz), the times and accuracies for calibration using Equation 6 and Equation 8 are listed in Table 7, where minimal tuning time is 1/8th of the VCO band spacing.

Table 7. Autocalibration Example with f_{XTAL} = 50 MHz, R = 1, m = 0

Across all VCOs, a measurement resolution better than 800 kHz produces correct results. Setting $m = 0$ and $n = 5$ provides 781 kHz of resolution and adds 8.6 μs of autocalibration time to a normal frequency hop. After the autocalibration sets the final switch value, 8.64 μs after the frequency change command, the fractional register is loaded, and the loop locks with a normal transient predicted by the loop dynamics. Therefore, as shown in this example, autocalibration typically adds about 8.6 μs to the normal time to achieve frequency lock. Use autocalibration for all but the most extreme frequency hopping requirements.

Manual VCO Calibration for Fast Frequency Hopping

When switching frequencies quickly is needed, it is possible to eliminate the autocalibration time by calibrating the VCO in advance and storing the switch number vs. frequency information in the host, which is accomplished by initially locking the HMC832A on each desired frequency using autocalibration, then reading and storing the selected VCO switch settings. The VCO switch settings are available in Register 0x10[7:0] after every autocalibration operation. The host must then program the VCO switch settings directly when changing frequencies.

Manual writes to the VCO switches are executed immediately as are writes to the integer and fractional registers when autocalibration is disabled. Therefore, frequency changes with manual control and autocalibration disabled requires a minimum of two serial port transfers to the PLL, once to set the VCO switches and once to set the PLL frequency.

When autocalibration is disabled (Register $0x0A[11] = 1$), the VCO updates its registers immediately with the value written via Register 0x05. The VCO internal transfer requires 16 VSCK clock cycles after the completion of a write to Register 0x05. VSCK and the autocalibration controller clock are equal to the input reference divided by 0, 4, 16, or 32 as controlled by Register 0x0A[14:13].

For settling time requirements faster than 1 ms, contact Analog Devices, Inc., applications support. Settling times under 100 µs are possible but certain conditions on performance do exist.

Registers Required for Frequency Changes in Fractional Mode

In fractional mode (Register $0x06[11] = 1$), a large change of frequency may require main serial port writes to one of the three following registers:

- The integer register, Register 0x03. This write is required only if the integer part changes.
- The VCO SPI register, Register 0x05. This write is required only for manual control of VCO if Register $0x0A[11] = 1$, autocalibration is disabled, or to change the VCO output divider value (VCO_REG 0x02). See Figure 39 for more information.
- The fractional register, Register 0x04. The fractional register write triggers autocalibration when Register $0x0A[11] = 0$, and it is loaded into the modulator automatically after the autocalibration runs. If autocalibration is disabled,

Register $0x0A[11] = 1$, the fractional frequency change is loaded immediately into the modulator when the register is written with no adjustment to the VCO.

Small steps in frequency in fractional mode, with autocalibration enabled (Register $0x0A[11] = 0$), usually require only a single write to the fractional register. In a worst case scenario, three main serial port transfers to the HMC832A may be required to change frequencies in fractional mode. If the frequency step is small and the integer part of the frequency does not change, the integer register is not changed. In all cases, in fractional mode, it is necessary to write to the fractional register, Register 0x04, for frequency changes.

Registers Required for Frequency Changes in Integer Mode

In integer mode (Register $0x06[11] = 0$), a change of frequency requires main serial port writes to the following registers:

- VCO SPI register, Register 0x05. This write is required only for manual control of the VCO when Register $0x0A[11] = 1$ (autocalibration disabled) or when the VCO output divider value must change (VCO_REG 0x02).
- Integer register, Register 0x03. In integer mode, an integer register write triggers autocalibration when Register $0x0A[11] = 0$ and it is loaded into the prescaler automatically after autocalibration runs. If autocalibration is disabled, Register $0x0A[11] = 1$, the integer frequency change is loaded into the prescaler immediately when written with no adjustment to the VCO. Normally, changes to the integer register cause large steps in the VCO frequency; therefore, the VCO switch settings must be adjusted. Autocalibration enabled is the recommended method for integer mode frequency changes. If autocalibration is disabled (Register $0x0A[11] = 1$), a prior knowledge of the correct VCO switch setting and the corresponding adjustment to the VCO is required before executing the integer frequency change.

VCO Output Mute Function

The HMC832A features an intelligent output mute function with the capability to disable the VCO output while maintaining fully functional PLL and VCO subsystems. The mute function is automatically controlled by the HMC832A and provides a variety of mute control options including

- Automatic mute. This option automatically mutes the outputs during VCO calibration during output frequency changes. This mode can be useful in eliminating any out of band emissions during frequency changes, and ensuring that the system emits only the desired frequencies. It is enabled by writing $VCO_REG 0x03[8:7] = 1d$.
- Always mute (VCO_REG $0x03[8:7] = 3d$). This mode is used for manual mute control.

Data Sheet **HMC832A**

Typical isolation when the HMC832A is muted is always better than −50 dB, and is approximately −40 dB better than disabling the individual outputs of the HMC832A via VCO_REG 0x03[3:2], as shown in Figure 35.

The VCO subsystem registers are not directly accessible. They are written to the VCO subsystem via PLL Register 0x05. See Figure 39 and the VCO Serial Port Interface (VSPI) section for more information about the VCO subsystem SPI.

VCO Built-In Self Test (BIST) with Autocalibration

The frequency limits of the VCO can be measured using the BIST features of the autocalibration machine by setting Register $0x0A[10] = 1$, which freezes the VCO switches in one position. VCO switches can then be written manually with the varactor biased at the nominal midrail voltage used for autocalibration. For example, to measure the VCO maximum frequency, use Switch 0, written to the VCO subsystem via Register 0x05 = 000000001 0000 VCO_ID, where VCO_ID = 000b.

When autocalibration is enabled (Register $0x0A[11] = 0$), and a new frequency is written, autocalibration runs. The VCO frequency error relative to the command frequency is measured and the results are written to Register 0x11[19:0], where Register 0x11[19] is the sign bit. The result is written in terms of VCO count error (see Equation 4).

For example, if the expected VCO is 2 GHz, the reference is 50 MHz, and n is 6, expect to measure $2000/(50/2^6) = 2560$ counts. If a difference of −5 counts is measured in Register 0x11, it means 2555 counts were actually measured. Therefore, the actual frequency of the VCO is 5/2560 low (negative), or 1.99609375 GHz. With a 2 GHz VCO, 50 MHz reference, and $n = 6$, one count is approximately ±781 kHz.

PLL SUBSYSTEM

Charge Pump (CP) and Phase Detector (PD)

The phase detector (PD) has two inputs, one from the reference path divider and one from the RF path divider. When in lock, these two inputs are at the same average frequency and are fixed at a constant average phase offset with respect to each other. The frequency of operation of the PD is f_{PD} . Most formulas related to, for example, step size, Σ - Δ modulation, and timers, are functions of the operating frequency of the PD, f_{PD} , f_{PD} is also referred to as the comparison frequency of the PD.

The PD compares the phase of the RF path signal with that of the reference path signal and controls the charge pump output current as a linear function of the phase difference between the two signals. The output current varies linearly over a full $\pm 2\pi$ radians (±360°) of input phase difference.

Charge Pump

A simplified diagram of the charge pump is shown in Figure 43. The CP consists of four programmable current sources: two controlling the CP gain (up gain, Register 0x09[13:7], and down gain, Register 0x09[6:0]) and two controlling the CP offset, where the magnitude of the offset is set by Register 0x09[20:14], and the direction is selected by Register $0x09[21] = 1$ for up offset and Register $0x09[22] = 1$ for down offset.

CP gain is used at all times, whereas CP offset is recommended for fractional mode of operation only. Typically, the CP up and down gain settings are set to the same value (Register 0x09[13:7] = Register 0x09[6:0]).

Charge Pump Gain

Charge pump up and down gains are set by Register 0x09[13:7] and Register 0x09[6:0], respectively. The current gain of the pump in amps/radian is equal to the gain setting of this register (Register 0x09) divided by 2π .

The typical CP gain setting is set from 2 mA to 2.5 mA; however, lower values can also be used. Note that values less than 1 mA may result in degraded phase noise performance.

For example, if both Register 0x09[13:7] and Register 0x09[6:0] are set to 50 decimal, the output current of each pump is 1 mA, and the phase frequency detector gain is $k_p = 1$ mA/2 π radians, or 159 μA/rad. See the Charge Pump (CP) and Phase Detector (PD) section for more information.

Figure 43. Charge Pump Gain and Offset Control

Charge Pump Phase Offset

In integer mode, the phase detector operates with zero offset. The divided reference signal and the divided VCO signal arrive at the phase detector inputs at the same time. Integer mode does not require any CP offset current. When operating in integer mode, disable the CP offset in both directions (up and down) by writing Register $0x09[22:21] = 00b$, and set the CP offset magnitude to zero by writing Register $0x09[20:14] = 0$.

In fractional mode, CP linearity is of paramount importance. Any nonlinearity degrades phase noise and spurious performance. These nonlinearities are eliminated by operating the PD with an average phase offset, either positive or negative (either the reference or the VCO edge always leads, that is, arrives first at the PD).

A programmable CP offset current source adds dc current to the loop filter and creates the desired phase offset. Positive current causes the VCO to lead, whereas negative current causes the reference to lead.

The CP offset is controlled via Register 0x09. Increasing the offset current causes the phase offset to scale from 0° to 360°.

The specific level of charge pump offset current (Register 0x09, Bits[20:14]) is calculated using Equation 9 and shown in Figure 44.

Required CP Offset = min ((4.3 × 10^{-9} × f_{pD} × I_{CP}), 0.25 × I_{CP}) (9) where:

 f_{PD} is the comparison frequency of the phase detector (Hz). I_{CP} is the full-scale current setting (A) of the switching charge pump (set in Register 0x09[6:0] and Register 0x09[13:7]).

Figure 44. Recommended CP Offset Current vs. Phase Detector Frequency for Typical CP Gain Currents, Calculated Using Equation 9

Do not allow the required CP offset current to exceed 25% of the programmed CP current. It is recommended to enable the up offset and disable the down offset by writing Register 0x09[22:21] = 01b.

Operation with CP offset influences the required configuration of the lock detect function. See the description of the lock detect function in the Lock Detect section.

Phase Detector Functions

Register 0x0B, the phase detector register, allows manual access to control special phase detector features.

Setting Register $0x0B[5] = 0$ masks the PD up output, which prevents the charge pump from pumping up.

Setting Register $0x0B[6] = 0$ masks the PD down output, which prevents the charge pump from pumping down.

Clearing both Register 0x0B[5] and Register 0x0B[6] tristates the charge pump while leaving all other functions operating internally.

The PD force CP up (Register $0x0B[9] = 1$) and force CP down (Register $0x0B[10] = 1$) bits allow the charge pump to be forced up or down, respectively. This forces the VCO to the ends of the tuning range, which is useful in testing the VCO.

Reference Input Stage

Figure 45. Reference Path Input Stage

The reference buffer provides the path from an external reference source (generally crystal-based) to the R divider, and eventually to the phase detector. The buffer has two modes of operation controlled by Register 0x08[21]. High gain (Register $0x08[21] = 0$) is recommended below 200 MHz, and high frequency (Register $0x08[21] = 1$) for 200 MHz to 350 MHz operation. The buffer is internally dc biased with 100 Ω internal termination. For a 50 Ω match, add an external 100 Ω resistor to ground followed by an ac coupling capacitor (impedance less than 1 Ω).

At low frequencies, a relatively square reference is recommended to maintain a high input slew rate. At higher frequencies, use a square or sinusoid. Table 8 shows the recommended operating regions for different reference frequencies. If operating outside these regions, the device usually still operates, but with degraded reference path phase noise performance.

When operating at 50 MHz, the input referred phase noise of the PLL is between −148 dBc/Hz and −150 dBc/Hz at a 10 kHz offset, depending on the mode of operation. To avoid degradation of the PLL noise contribution, the input reference signal must be 10 dB better than this floor. Such low levels are only necessary if the PLL is the dominant noise contributor and these levels are required for the system goals.

Reference Path R Divider

The reference path R divider is based on a 14-bit counter and can divide input signals by values from 1 to 16,383 and is controlled via Register 0x02.

RF Path, N Divider

The main RF path divider is capable of average divide ratios between 2^{19} – 5 (524,283) and 20 in fractional mode, and between 2^{19} – 1 (524,287) and 16 in integer mode. The VCO frequency range divided by the minimum N divider value places practical restrictions on the maximum usable PD frequency. For example, a VCO operating at 1.5 GHz in fractional mode with a minimum N divider value of 20 has a maximum PD frequency of 75 MHz.

Lock Detect

The lock detect (LD) function verifies that the HMC832A is generating the desired frequency. It is enabled by writing Register $0x07[3] = 1$. The HMC832A provides an LD indicator in one of two ways.

- As an output available on the LD/SDO pin of the HMC832A (configuration is required to use the LD/SDO pin for LD purposes; for more information, see the Serial Port and the Configuring the LD/SDO Pin for LD Output sections).
- Reading from Register $0x12[1]$, where Bit $1 = 1$ indicates a locked condition and Bit $1 = 0$ indicates an unlocked condition.

The LD circuit expects the divided VCO edge and the divided reference edge to appear at the PD within a user specified time period (window), repeatedly. Either signal may arrive first. Only the difference in arrival times is significant. The arrival of the two edges within the designated window increments an internal counter. When the count reaches and exceeds a user specified value (Register 0x07[2:0]), the HMC832A declares lock.

Failure in registering the two edges in any one window resets the counter and immediately declares an unlocked condition. Lock is deemed to be reestablished when the counter reaches the user specified value (Register 0x07[2:0]) again.

The HMC832A supports two lock detect modes.

- Analog LD supports a fixed window size of 10 ns. Analog LD mode is selected by writing Register $0x07[6] = 0$.
- Digital LD supports a user configurable window size, programmed in Register 0x07[11:7]. Digital LD is selected by writing Register $0x07[6] = 1$.

Lock Detect Configuration

Optimal spectral performance in fractional mode requires CP current and CP offset current configuration, described in detail in the Charge Pump (CP) and Phase Detector (PD) section.

The settings in Register 0x09 impact the required LD window size in fractional mode of operation. To function, the required lock detect window size is provided by Equation 10 in fractional mode and Equation 11 in integer mode.

LD Window (sec) =
\n
$$
\frac{I_{CP_OFFSET}(A)}{f_{PD}(Hz) \times I_{CP}(A)} + 2.66 \times 10^{-9} (\text{sec}) + \frac{1}{f_{PD}(Hz)}
$$
\n
$$
\frac{1}{2}
$$
\n(10)

LD Window (sec) =
$$
\frac{1}{2 \times f_{PD}}
$$
 (11)

where:

 f_{PD} is the comparison frequency of the phase detector. $I_{CP~OFF}$ is the charge pump offset current (Register 0x09[20:14]). I_{CP} is the full-scale current setting of the switching charge pump (Register 0x09[6:0] or Register 0x09[13:7]).

If the result provided by Equation 10 is equal to 10 ns, analog LD can be used (Register $0x07[6] = 0$); otherwise, digital LD is necessary (Register $0x07[6] = 1$).

Table 9 lists the required Register 0x07 settings to appropriately program the digital LD window size. From Table 9, select the closest value in the digital LD window size columns to the ones calculated in Equation 10 and Equation 11, and program Register 0x07[11:10] and Register 0x07[9:7] accordingly.

Table 8. Reference Sensitivity¹

¹ Okay means the setting works. For example, 150 MHz input square wave is sufficient but 100 MHz may provide improved performance.

Digital Window Configuration Example

For this example, assume the device is in fractional mode, with a 50 MHz PD and the following conditions:

- Charge pump gain of 2 mA (Register $0x09[13:7] = 0x64$, Register $0x09[6:0] = 0x64$),
- Up offset (Register $0x09[22:21] = 01b$)
- Offset current magnitude of 400 μA (Register 0x09[20:14] $= 0x50$

Apply Equation 10 to calculate the required LD window size.

 LD Window (sec) =

$$
\left(\frac{0.4\times10^{-3}(A)}{50\times10^{6}(Hz)\times2\times10^{-3}(A)}+2.66\times10^{-9}(\text{sec})+\frac{1}{50\times10^{6}(Hz)}\right)
$$

$$
= 13.33 \text{ ns}
$$

Locate the Table 9 value that is closest to this result, which is, in this case, $13.3 \approx 13.33$. To set the digital LD window size, program Register $0x07[11:10] = 10b$ and Register $0x07[9:7] =$ 010b, according to Table 9. For a given operating point, there is always a good solution for the lock detect window. However, one solution does not fit all operating points. As observed from Equation 10 and Equation 11, if the charge pump offset or PD frequency is changed significantly, the lock detect window may need to be adjusted.

Configuring the LD/SDO Pin for LD Output

Setting Register $0x0F[7] = 1$ and Register $0x0F[4:0] = 1$ displays the lock detect flag on the LD/SDO pin of the HMC832A. When locked, LD/SDO is high. As the name suggests, the LD/SDO pin is multiplexed between the LD and the serial data output (SDO) signals. Therefore, LD is available on the LD/SDO pin at all times except when a serial port read is requested, in which case the pin reverts temporarily to the serial data output pin, and returns to the lock detect flag after the read is completed.

LD can be made available on the LD/SDO pin at all times by writing Register $0x0F[6] = 1$. In that case, the HMC832A does not provide any readback functionality because the SDO signal is not available.

Cycle Slip Prevention (CSP)

When changing the VCO frequency and the VCO is not yet locked to the reference, the instantaneous frequencies of the two PD inputs are different, and the phase difference of the two inputs at the PD varies rapidly over a range much greater than $±2π$ radians. Because the gain of the PD varies linearly with phase up to $±2π$, the gain of a conventional PD cycles from high gain, when the phase difference approaches a multiple of 2π, to low gain, when the phase difference is slightly larger than a multiple of 0 radians. The output current from the charge pump cycles from maximum to minimum, even though the VCO has not yet reached its final frequency.

The charge on the loop filter small capacitor may actually discharge slightly during the low gain portion of the cycle. This discharge can make the VCO frequency reverse temporarily during locking. This phenomenon is known as cycle slipping. Cycle slipping causes the pull-in rate during the locking phase to vary cyclically. Cycle slipping increases the time to lock to a value greater than that predicted by normal small signal Laplace transform analysis.

The HMC832A PD features an ability to reduce cycle slipping during acquisition. The cycle slip prevention (CSP) feature increases the PD gain during large phase errors. The specific phase error that triggers the momentary increase in PD gain is set via Register 0x0B[8:7].

Frequency Tuning

The HMC832A VCO subsystem always operates in the fundamental frequency of operation (1500 MHz to 3000 MHz). The HMC832A generates frequencies below its fundamental frequency (25 MHz to 1500 MHz) by tuning to the appropriate fundamental frequency and selecting the appropriate output divider setting (divide by 2 to 62) in VCO_REG 0x02[5:0].

The HMC832A automatically controls frequency tuning in the fundamental band of operation. For more information, see the VCO Autocalibration section.

To tune to frequencies below the fundamental frequency range (<1500 MHz), it is required to tune the HMC832A to the appropriate fundamental frequency, and then select the appropriate output divider setting (divide by 2 to 62) in VCO_REG 0x02[5:0].

Table 9. Typical Digital Lock Detect Window
