

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices please contact your nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements components may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies Office.

Infineon Technologies Components may only be used in life-support devices or systems with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system, or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body, or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Single-Stage Flyback And PFC Controller

Product Highlight

- Quasi-Resonant Control For Highly Efficient LED Driving Solutions
- Primary Side Flyback Control With Integrated PFC And Phase-Cut Dimming
- Integrated HV Startup Cell For Short Time To Light
- Best In Class System BOM For Dimmable LED Bulb

ICL8001G

PG-DSO-8

Features

- High, stable efficiency over wide operating range
- Optimized for trailing- and leading-edge dimmer
- Precise PWM for primary PFC and dimming control
- Power cell for Vcc pre-charging with constant current
- Built-in digital soft-start
- Foldback correction and cycle-by-cycle peak current limitation
- VCC over/ under-voltage lockout
- Auto restart mode for short circuit protection
- Adjustable latch-off mode for output overvoltage protection

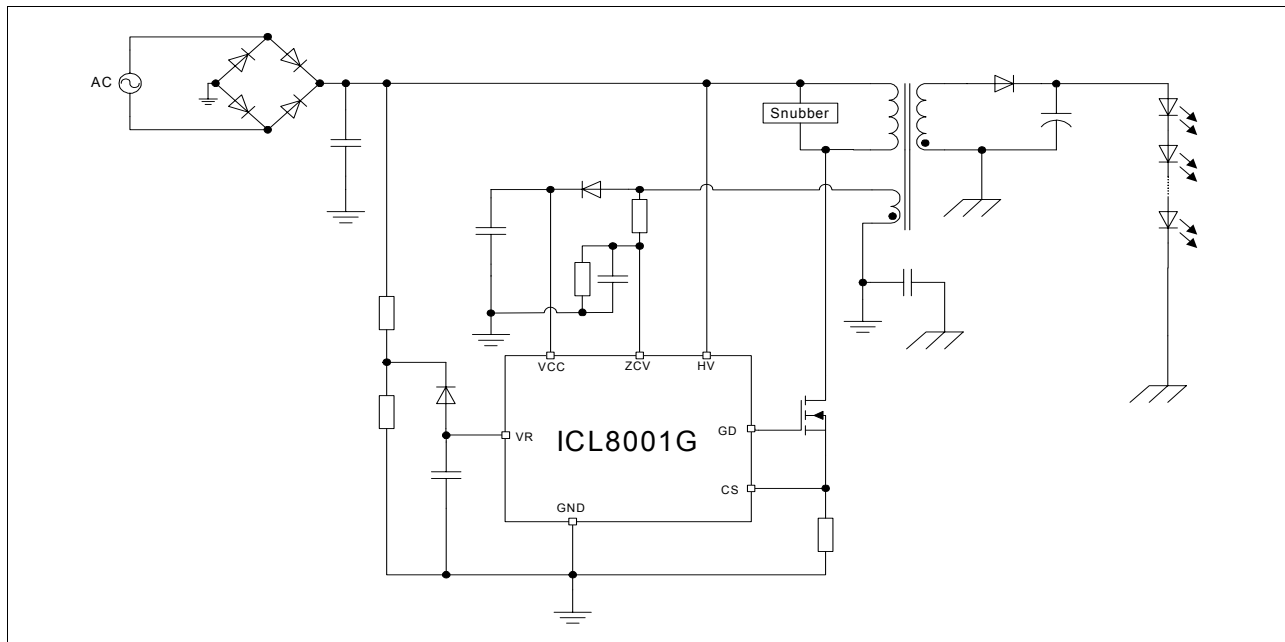

Description

The ICL8001G employs quasi-resonant operation mode optimized for off-line LED lighting, especially dimmable LED bulbs for incandescent lamp replacement.

Precise PWM generation enables primary control for phase cut dimming and high power factor $PF > 98\%$. Significant improved driver efficiency, up to 90%, compared to other conventional solutions. The product has a wide operation range (up to 26V) of IC voltage supply and lower power consumption. Multiple safety functions ensure a full system protection in failure situations.

With its full feature set and simple application, the ICL8001G represents an outstanding choice for quasi-resonant flyback LED bulb designs combining feature set and performance at minimum BOM cost.

Pin Configuration and Functionality

1 Pin Configuration and Functionality

1.1 Pin Configuration with PG-DSO-8

Pin	Symbol	Function
1	ZCV	Zero Crossing
2	VR	Voltage Sense
3	CS	Current Sense
4	GD	Gate Drive Output
5	HV	High Voltage Input
6	n.c.	Not connected
7	VCC	Controller Supply Voltage
8	GND	Controller Ground

1.2 Package PG-DSO-8

Figure 1 Pin Configuration PG-DSO-8(top view)

1.3 Pin Functionality

ZCV (Zero Crossing)

At this pin, the voltage from the auxiliary winding after a time delay circuit is applied. Internally, this pin is connected to the zero-crossing detector for switch-on determination. Additionally, the output overvoltage detection is realized by comparing the voltage V_{zc} with an internal preset threshold.

VR (Voltage Sense)

The rectified input mains voltage is sensed at this pin. The signal is used to set the peak current of the peak-current control and therefore allow for the PFC and phase-cut dimming functionality.

CS (Current Sense)

This pin is connected to the shunt resistor for the primary current sensing, externally, and the PWM signal generator for switch-off determination (together with the feedback voltage), internally. Moreover, short-winding protection is realised by monitoring the voltage V_{cs} during on-time of the main power switch.

GD (Gate Drive Output)

This output signal drives the external main power switch, which is a power MOSFET in most case.

HV (High Voltage)

The pin HV is connected to the bus voltage, externally, and to the power cell, internally. The current through this pin pre-charges the VCC capacitor with constant current once the supply bus voltage is applied.

VCC (Power supply)

VCC pin is the positive supply of the IC. The operating range is between V_{VCCoff} and V_{VCCOV} .

GND (Ground)

This is the common ground of the controller.

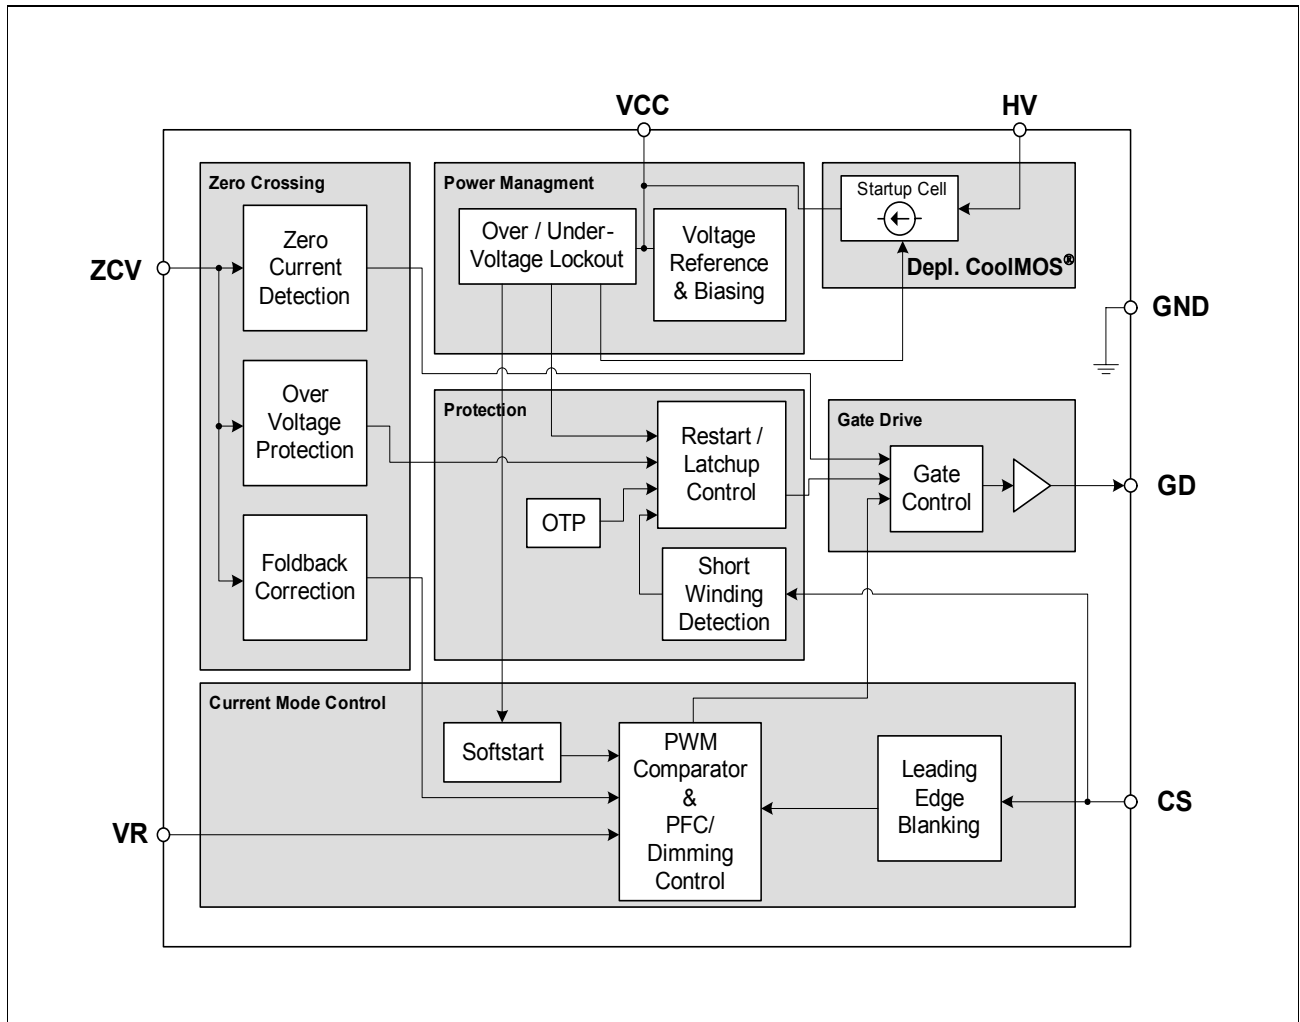

Figure 2 Representative Block Diagram

3 Functional Description

3.1 VCC Pre-Charging and Typical VCC Voltage During Start-up

In ICL8001G, a high voltage startup cell is integrated. As shown in Figure 2, the start cell consists of a high voltage device and a controller, whereby the high voltage device is controlled by the controller. The startup cell provides a pre-charging of the VCC capacitor till VCC voltage reaches the VCC turned-on threshold V_{VCCon} and the IC begins to operate.

Once the mains input voltage is applied, a rectified voltage shows across the capacitor C_{bus} . The high voltage device provides a current to charge the VCC capacitor C_{VCC} . Before the VCC voltage reaches a certain value, the amplitude of the current through the high voltage device is only determined by its channel resistance and can be as high as several mA. After the VCC voltage is high enough, the controller controls the high voltage device so that a constant current around 1mA is provided to charge the VCC capacitor further, until the VCC voltage exceeds the turned-on threshold V_{VCCon} . As shown as the time phase I in Figure 3, the VCC voltage increase near linearly and the charging speed is independent of the mains voltage level.

Figure 3 VCC voltage at start up

The time taking for the VCC pre-charging can then be approximately calculated as:

$$t_1 = \frac{V_{VCCon} \cdot C_{VCC}}{I_{VCCcharge2}} \quad [1]$$

where $I_{VCCcharge2}$ is the charging current from the startup cell which is 1.05mA, typically.

Exceeds the VCC voltage the turned-on threshold V_{VCCon} of at time t_1 , the startup cell is switched off, and the IC begins to operate with a soft-start. Due to power consumption of the IC and the fact that still no energy from the auxiliary winding to charge the VCC capacitor before the output voltage is built up, the VCC voltage drops (Phase II). Once the output voltage is high enough, the VCC capacitor receives then energy from the auxiliary winding from the time point t_2 on. The VCC

then will reach a constant value depending on output load.

3.2 Soft-start

At the time t_{on} , the IC begins to operate with a soft-start. By this soft-start the switching stresses for the switch, diode and transformer are minimised. The soft-start implemented in ICL8001G is a digital time-based function. The preset soft-start time is **12ms** with 4 steps. If not limited by other functions, the peak voltage on CS pin will increase step by step from 0.32V to 1V finally.

Figure 4 Maximum current sense voltage during softstart

3.3 Normal Operation

The PWM controller during normal operation consists of a digital signal processing circuit including a comparator, and an analog circuit including a current measurement unit and a comparator. The switch-on and -off time points are each determined by the digital circuit and the analog circuit, respectively. As input information for the switch-on determination, the zero-crossing input signal is needed, while the voltages sense signal at pin VR and the current sensing signal V_{CS} are necessary for the switch-off determination. Details about the full operation of the PWM controller in normal operation are illustrated in the following paragraphs.

3.3.1 Zero crossing

In the system, the voltage from the auxiliary winding is applied to the zero-crossing pin through a RC network, which provides a time delay to the voltage from the auxiliary winding. Internally, this pin is connected to a clamping network, a zero-crossing detector, an output overvoltage detector and a ringing suppression time controller.

During on-state of the power switch a negative voltage applies to the ZCV pin. Through the internal clamping network, the voltage at the pin is clamped to certain level.

The voltage v_{ZC} is also used for the output overvoltage protection. Once the voltage at this pin is higher than the threshold V_{ZCOVP} during off-time of the main switch, the IC is latched off after a fixed blanking time.

To achieve the switch-on at voltage valley, the voltage from the auxiliary winding is fed to a time delay network (the RC network consists of D_{ZC} , R_{ZC1} , R_{ZC2} and C_{ZC} as shown in typical application circuit) before it is applied to the zero-crossing detector through the ZC pin. The needed time delay to the main oscillation signal Δt should be approximately one fourth of the oscillation period (by transformer primary inductor and drain-source capacitor) minus the propagation delay from the detected zero-crossing to the switch-on of the main switch t_{delay} , theoretically:

$$\Delta t = \frac{T_{osc}}{4} - t_{delay} \quad [2]$$

This time delay should be matched by adjusting the time constant of the RC network which is calculated as:

$$\tau_{td} = C_{ZC} \cdot \frac{R_{ZC1} \cdot R_{ZC2}}{R_{ZC1} + R_{ZC2}} \quad [3]$$

3.3.2 Ringing suppression time

After MOSFET is turned off, there will be some oscillation on V_{DS} , which will also appear on the voltage on ZC pin. To avoid that the MOSFET is turned on mistriggered by such oscillations, a ringing suppression timer is implemented. The timer is dependent on the voltage v_{ZC} . When the voltage v_{ZC} is lower than the threshold V_{ZCRS} , a longer preset time applies, while a shorter time is set when the voltage v_{ZC} is higher than the threshold.

3.3.2.1 Switch on determination

After the gate drive goes to low, it can not be changed to high during ringing suppression time.

After ring suppression time, the gate drive can be turned on when the zero crossing is detected.

However, it is also possible that the oscillation between primary inductor and drain-source capacitor damps very fast and IC can not detect a zero crossing. In this case, a maximum off time is implemented. After gate drive has been remained off for the period of T_{OffMax} , the gate drive will be turned on again regardless. This function can effectively prevent the switching frequency from going lower than 20kHz, otherwise which will cause audible noise, during start up.

3.3.3 Switch Off Determination

In the converter system, the primary current is sensed by an external shunt resistor, which is connected between low-side terminal of the main power switch

and the common ground. The sensed voltage across the shunt resistor v_{CS} is applied to an internal current measurement unit, and its output voltage V_1 is compared with the voltage at pin VR. Once the voltage V_1 exceeds the voltage V_{VR} , the output flip-flop is reset. As a result, the main power switch is switched off. The relationship between the V_1 and the v_{CS} is described by:

$$V_1 = 3,3 \cdot V_{CS} + 0,7 \quad [4]$$

To avoid mistriggering caused by the voltage spike across the shunt resistor at the turn on of the main power switch, a leading edge blanking time, t_{LEB} , is applied to the output of the comparator. In other words, once the gate drive is turned on, the minimum on time of the gate drive is the leading edge blanking time.

In addition, there is a maximum on time, t_{OnMax} , limitation implemented in the IC. Once the gate drive has been in high state longer than the maximum on time, it will be turned off to prevent the switching frequency from going too low because of long on time.

3.4 Current Limitation

There is a cycle by cycle current limitation realized by the current limit comparator to provide an overcurrent detection. The source current of the MOSFET is sensed via a sense resistor R_{CS} . By means of R_{CS} the source current is transformed to a sense voltage V_{CS} which is fed into the pin CS. If the voltage V_{CS} exceeds an internal voltage limit, adjusted according to the Mains voltage, the comparator immediately turns off the gate drive.

To prevent the Current Limitation process from distortions caused by leading edge spikes, a Leading Edge Blanking time (t_{LEB}) is integrated in the current sensing path.

A further comparator is implemented to detect dangerous current levels (V_{CSSW}) which could occur if one or more transformer windings are shorted or if the secondary diode is shorted. To avoid an accidental latch off, a spike blanking time of t_{CSSW} is integrated in the output path of the comparator.

3.4.1 Foldback Point Correction

When the main bus voltage increases, the switch on time becomes shorter and therefore the operating frequency is also increased. As a result, for a constant primary current limit, the maximum possible output power is increased, which the converter may have not been designed to support.

To avoid such a situation, the internal foldback point correction circuit varies the V_{CS} voltage limit according to the bus voltage. This means the V_{CS} will be decreased when the bus voltage increases. To keep a constant maximum input power of the converter, the

required maximum V_{CS} versus various input bus voltage can be calculated, which is shown in **Figure 5**.

Figure 5 Variation of the VCS limit voltage according to the IZC current

According to the typical application circuit, when MOSFET is turned on, a negative voltage proportional to bus voltage will be coupled to auxiliary winding. Inside ICL8001G, an internal circuit will clamp the voltage on ZC pin to nearly 0V. As a result, the current flowing out from ZC pin can be calculated as

$$I_{ZC} = \frac{V_{BUS} N_a}{R_{ZC1} N_p} \quad [5]$$

When this current is higher than I_{ZC-1} , the amount of current exceeding this threshold is used to generate an offset to decrease the maximum limit on V_{CS} . Since the ideal curve shown in **Figure 5** is a nonlinear one, a digital block in ICL8001G is implemented to get a better control of maximum output power. Additional advantage to use digital circuit is the production tolerance is smaller compared to analog solutions. The typical maximum limit on V_{CS} versus the ZC current is shown in **Figure 6**.

Figure 6 V_{CS-max} versus I_{ZC}

3.5 Protection Functions

The IC provides full protection functions. The following table summarizes these protection functions.

Table 1 Protection features

VCC Overvoltage	Auto Restart Mode
VCC Undervoltage	Auto Restart Mode
Over temperature	Auto Restart Mode
Output Overvoltage	Latched Off Mode
Short Winding	Latched Off Mode

During operation, the VCC voltage is continuously monitored. In case of an under- or an over-voltage, the IC is reset and the main power switch is then kept off. After the VCC voltage falls below the threshold V_{VCCoff} , the startup cell is activated. The VCC capacitor is then charged up. Once the voltage exceeds the threshold V_{VCCon} , the IC begins to operate with a new soft-start.

During off-time of the power switch, the voltage at the zero-crossing pin is monitored for output over-voltage detection. If the voltage is higher than the preset threshold V_{ZCOVP} , the IC is latched off after the preset blanking time.

If the junction temperature of IC exceeds $140^{\circ}C$, the IC enter into autorestart mode.

If the voltage at the current sensing pin is higher than the preset threshold V_{CSSW} during on-time of the power switch, the IC is latched off. This is short-winding protection.

During latch-off protection mode, when the VCC voltage drops to 10.5V, the startup cell is activated and the VCC voltage is charged to 18V then the startup cell is shut down again and repeats the previous procedure.

There is also a maximum on time limitation inside ICL8001G. Once the gate voltage is high longer than t_{OnMAX} , it is turned off immediately.

4 Electrical Characteristics

Note: All voltages are measured with respect to ground (Pin 8). The voltage levels are valid if other ratings are not violated.

4.1 Absolute Maximum Ratings

Note: Absolute maximum ratings are defined as ratings, which when being exceeded may lead to destruction of the integrated circuit. For the same reason make sure, that any capacitor that will be connected to pin 7 (VCC) is discharged before assembling the application circuit.

Parameter	Symbol	Limit Values		Unit	Remarks
		min.	max.		
HV Voltage	V_{HV}	-	500	V	
VCC Supply Voltage	V_{VCC}	-0.3	27	V	
FB Voltage	V_{FB}	-0.3	5.0	V	
ZCV Voltage	V_{ZC}	-0.3	5.0	V	
CS Voltage	V_{CS}	-0.3	5.0	V	
GD Voltage	V_{OUT}	-0.3	27	V	
Maximum current out from ZC pin	$I_{ZC_{MAX}}$	3	-	mA	
Junction Temperature	T_j	-40	125	°C	
Storage Temperature	T_s	-55	150	°C	
Thermal Resistance Junction -Ambient	R_{thJA}	-	185	K/W	PG-DSO-8
ESD Capability (incl. Drain Pin)	V_{ESD}	-	2	kV	Human body model ¹⁾

¹⁾ According to EIA/JESD22-A114-B (discharging a 100pF capacitor through a 1.5kΩ series resistor)

4.2 Operating Range

Note: Within the operating range the IC operates as described in the functional description.

Parameter	Symbol	Limit Values		Unit	Remarks
		min.	max.		
VCC Supply Voltage	V_{VCC}	$V_{VCC_{off}}$	$V_{VCC_{OV_P}}$	V	
Junction Temperature of Controller	T_{jCon}	-25	125	°C	

Electrical Characteristics

4.3 Characteristics

4.3.1 Supply Section

Note: The electrical characteristics involve the spread of values within the specified supply voltage and junction temperature range T_j from $-25\text{ }^\circ\text{C}$ to $125\text{ }^\circ\text{C}$. Typical values represent the median values, which are related to $25\text{ }^\circ\text{C}$. If not otherwise stated, a supply voltage of $V_{CC} = 18\text{ V}$ is assumed.

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Start Up Current	$I_{VCCstart}$	-	300	550	μA	$V_{VCC} = V_{VCCon} - 0.2\text{V}$
VCC Charge Current	$I_{VCCcharge1}$	-	5.0	-	mA	$V_{VCC} = 0\text{V}$
	$I_{VCCcharge2}$	0.8	-	-	mA	$V_{VCC} = 1\text{V}$
	$I_{VCCcharge3}$	-	1.0	-	mA	$V_{VCC} = V_{VCCon} - 0.2\text{V}$

Total Quality Management

Qualität hat für uns eine umfassende Bedeutung. Wir wollen allen Ihren Ansprüchen in der bestmöglichen Weise gerecht werden. Es geht uns also nicht nur um die Produktqualität – unsere Anstrengungen gelten gleichermaßen der Lieferqualität und Logistik, dem Service und Support sowie allen sonstigen Beratungs- und Betreuungsleistungen.

Dazu gehört eine bestimmte Geisteshaltung unserer Mitarbeiter. Total Quality im Denken und Handeln gegenüber Kollegen, Lieferanten und Ihnen, unserem Kunden. Unsere Leitlinie ist jede Aufgabe mit „Null Fehlern“ zu lösen – in offener Sichtweise auch über den eigenen Arbeitsplatz hinaus – und uns ständig zu verbessern.

Unternehmensweit orientieren wir uns dabei auch an „top“ (Time Optimized Processes), um Ihnen durch größere Schnelligkeit den entscheidenden Wettbewerbsvorsprung zu verschaffen.

Geben Sie uns die Chance, hohe Leistung durch umfassende Qualität zu beweisen.

Wir werden Sie überzeugen.

Quality takes on an all-encompassing significance at Semiconductor Group. For us it means living up to each and every one of your demands in the best possible way. So we are not only concerned with product quality. We direct our efforts equally at quality of supply and logistics, service and support, as well as all the other ways in which we advise and attend to you.

Part of this is the very special attitude of our staff. Total Quality in thought and deed, towards co-workers, suppliers and you, our customer. Our guideline is “do everything with zero defects”, in an open manner that is demonstrated beyond your immediate workplace, and to constantly improve.

Throughout the corporation we also think in terms of Time Optimized Processes (top), greater speed on our part to give you that decisive competitive edge.

Give us the chance to prove the best of performance through the best of quality – you will be convinced.

<http://www.infineon.com>
