

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# ADC1004S030/040/050

Single 10 bits ADC, up to 30 MHz, 40 MHz or 50 MHz

Rev. 04 — 2 July 2012

Product data sheet

## 1. General description

---

The ADC1004S030/040/050 are a family of 10-bit high-speed low-power Analog-to-Digital Converters (ADC) for professional video and other applications. They convert the analog input signal into 10-bit binary-coded digital signals at a maximum sampling rate of 50 MHz. All digital inputs and outputs are Transistor-Transistor Logic (TTL) and CMOS compatible, although a low-level sine wave clock input signal is allowed.

The device requires an external source to drive its reference ladder. If the application requires that the reference is driven via internal sources, Integrated Device Technology recommends you use one of the ADC1003S030/040/050 family.

## 2. Features

---

- 10-bit resolution
- Sampling rate up to 50 MHz
- DC sampling allowed
- One clock cycle conversion only
- High signal-to-noise ratio over a large analog input frequency range (9.4 effective bits at 4.43 MHz full-scale input at  $f_{clk} = 40$  MHz)
- No missing codes guaranteed
- In-Range (IR) CMOS output
- TTL and CMOS levels compatible digital inputs
- 3 V to 5 V CMOS digital outputs
- Low-level AC clock input signal allowed
- External reference voltage regulator
- Power dissipation only 175 mW (typical)
- Low analog input capacitance, no buffer amplifier required
- No sample-and-hold circuit required

## 3. Applications

---

- Video data digitizing
- Radar
- Transient signal analysis
- $\Sigma\Delta$  modulators
- Medical imaging
- Barcode scanner
- Global Positioning System (GPS) receiver

- Cellular base stations

- [1] In addition to a good layout of the digital and analog ground, it is recommended that the rise and fall times of the clock must not be less than 0.5 ns.
- [2] Analog input voltages producing code 0 up to and including code 1023:
- $V_{offset}$  BOTTOM is the difference between the analog input which produces data equal to 00 and the reference voltage on pin RB ( $V_{RB}$ ) at  $T_{amb} = 25$  °C.
  - $V_{offset}$  TOP is the difference between the reference voltage on pin RT ( $V_{RT}$ ) and the analog input which produces data outputs equal to code 1023 at  $T_{amb} = 25$  °C.
- [3] In order to ensure the optimum linearity performance of such converter architecture the lower and upper extremities of the converter reference resistor ladder (corresponding to output codes 0 and 1023 respectively) are connected to pins RB and RT via offset resistors  $R_{OB}$  and  $R_{OT}$  as shown in Figure 3.

a) The current flowing into the resistor ladder is  $I = \frac{V_{RT} - V_{RB}}{R_{OB} + R_L + R_{OT}}$  and the full-scale input range at the converter, to cover code 0

to 1023 is  $V_I = R_L \times I_L = \frac{R_L}{R_{OB} + R_L + R_{OT}} \times (V_{RT} + V_{RB}) = 0.852 \times (V_{RT} - V_{RB})$

b) Since  $R_L$ ,  $R_{OB}$  and  $R_{OT}$  have similar behavior with respect to process and temperature variation, the ratio  $\frac{R_L}{R_{OB} + R_L + R_{OT}}$  will be kept reasonably constant from device to device. Consequently, the variation of the output codes at a given input voltage depends mainly on the difference  $V_{RT} - V_{RB}$  and its variation with temperature and supply voltage. When several ADCs are connected in parallel and fed with the same reference source, the matching between each of them is optimized.

$$[4] \quad E_G = \frac{(V_{1023} - V_0) - V_{i(p-p)}}{V_{i(p-p)}} \times 100$$

- [5] The analog bandwidth is defined as the maximum input sine wave frequency which can be applied to the device. No glitches greater than 2 LSB, neither any significant attenuation are observed in the reconstructed signal.
- [6] The analog input settling time is the minimum time required for the input signal to be stabilized after a sharp full-scale input (square wave signal) in order to sample the signal and obtain correct output data.

- [7] Effective bits are obtained via a Fast Fourier Transform (FFT) treatment taking 8000 acquisition points per equivalent fundamental period. The calculation takes into account all harmonics and noise up to half of the clock frequency (Nyquist frequency). Conversion to signal-to-noise ratio:  $SINAD = ENOB \times 6.02 + 1.76$  dB.
- [8] Intermodulation measured relative to either tone with analog input frequencies of 4.43 MHz and 4.53 MHz. The two input signals have the same amplitude and the total amplitude of both signals provides full-scale to the converter.
- [9] Measurement carried out using video analyzer VM700A, where the video analog signal is reconstructed through a digital-to-analog converter.
- [10] Output data acquisition: the output data is available after the maximum delay time of  $t_{d(max)}$ . For 50 MHz version Integrated Device Technology recommends the lowest possible output load.
