BUFFER POWER-UP STATE MACHINE[1]

| State	Description
State0	Power off
State1	After 3.3V supply is detected to rise above 1.8-2V, the buffer enters state1 and initiates a 0.2ms-0.3ms delay. The total power up latency from power on to all outputs active must be less than 1ms (assume SRC_IN is available)
State2	Buffer waits for a valid clock on the SRC_IN input and PD de-assertion.
State3	Only after SRC_IN and power valid, PD de-asserted with the current mirror stable, or PLL lock, the DIF outputs are enabled

NOTE:

1. The total power up latency from power on to all outputs active must be less than 1ms (assuming a valid clock is present on CLK_IN input). If power is valid and Pwrdwn is de-asserted but no input clocks are present on the CLK_IN input, DIF clocks must remain disabled. Only after valid input clocks are detected, valid power, Pwrdwn# de-asserted with the PLL locked/stable and the DIF outputs enabled (doesn't apply to bypass mode).
