

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## 1.5A SWITCH STEP DOWN SWITCHING REGULATOR

### 1 General Features

- 1.5A INTERNAL SWITCH
- OPERATING INPUT VOLTAGE FROM 4.4V TO 36V
- 3.3V / ( $\pm 2\%$ ) REFERENCE VOLTAGE
- OUTPUT VOLTAGE ADJUSTABLE FROM 1.235V TO 35V
- LOW DROPOUT OPERATION: 100% DUTY CYCLE
- 500KHz INTERNALLY FIXED FREQUENCY
- VOLTAGE FEEDFORWARD
- ZERO LOAD CURRENT OPERATION
- INTERNAL CURRENT LIMITING
- INHIBIT FOR ZERO CURRENT CONSUMPTION
- SYNCHRONIZATION
- PROTECTION AGAINST FEEDBACK DISCONNECTION
- THERMAL SHUTDOWN

#### 1.1 APPLICATIONS:

- CONSUMER: STB, DVD, TV, VCR, CAR RADIO, LCD MONITORS
- NETWORKING: XDSL, MODEMS, DC-DC MODULES
- COMPUTER: PRINTERS, AUDIO/GRAPHIC CARDS, OPTICAL STORAGE, HARD DISK DRIVE
- INDUSTRIAL: CHARGERS, CAR BATTERY DC-DC CONVERTERS

Figure 1. Package

Table 1. Order Codes

Part Number	Package
L5970AD	SO-8
L5970ADTR	SO-8 in Tape & Reel

### 2 Description

The L5970AD is a step down monolithic power switching regulator with a switch current limit of 1.5A so it is able to deliver more than 1A DC current to the load depending on the application conditions.

The output voltage can be set from 1.235V to 35V.

The device uses an internal P-Channel D-MOS transistor (with a typical  $R_{DS(ON)}$  of 200m $\Omega$ ) as switching element to avoid the use of bootstrap capacitor and guarantee high efficiency.

An internal oscillator fixes the switching frequency at 500KHz to minimize the size of external components. Having a minimum input voltage of 4.4V only, it is particularly suitable for 5V bus, available in all computer related applications.

Pulse by pulse current limit with the internal frequency modulation offers an effective constant current short circuit protection.

Figure 2. Test and Application Circuit

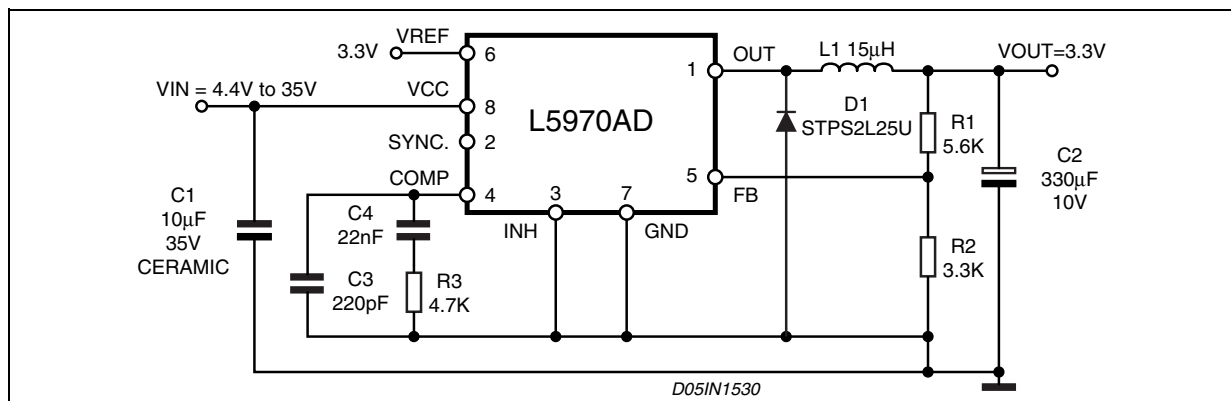

Table 2. Thermal Data

Symbol	Parameter	Value	Unit
$R_{th(j-amb)}$	Thermal Resistance Junction to ambient Max.	120 (*)	°C/W

(\*) Package mounted on board

Figure 3. Pin Connection (top view)

Table 3. Pin Description

N.	Name	Description
1	OUT	Regulator Output.
2	SYNC	Master/Slave Synchronization. When it is open, a signal synchronous with the turn-off of the internal power is present at the pin. When connected to an external signal at a frequency higher than the internal one, then the device is synchronized by the external signal. Connecting together the SYNC pin of two devices, the one with the higher frequency works as master and the other one, works as slave.
3	INH	A logical signal (active high) disables the device. With INH higher than 2.2V the device is OFF and with INH lower than 0.8V, the device is ON. If INH is not used the pin must be grounded. When it is open, an internal pull-up disables the device.
4	COMP	E/A output to be used for frequency compensation.
5	FB	Stepdown feedback input. Connecting the output voltage directly to this pin results in an output voltage of 1.235V. An external resistor divider is required for higher output voltages (the typical value for the resistor connected between this pin and ground is 4.7K).
6	$V_{REF}$	Reference voltage of 3.3V. No filter capacitor is needed to stability.
7	GND	Ground.
8	$V_{CC}$	Unregulated DC input voltage.

Table 4. Absolute Maximum Ratings

	Short Circuit Current		10	18	30	mA

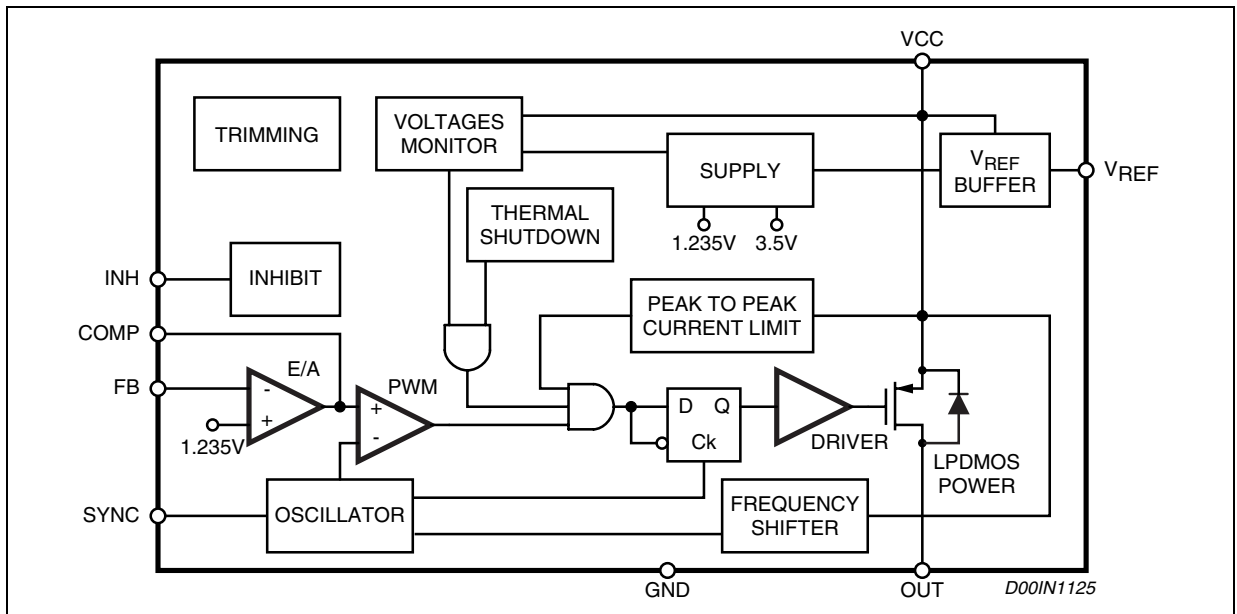

Note: 1. Guaranteed by design

### 3 Functional Description

The main internal blocks are shown in Fig. 4, where is reported the device block diagram. They are:

- A voltage regulator that supplies the internal circuitry. From this regulator, a 3.3V reference voltage is externally available.
- A voltage monitor circuit that checks the input and internal voltages.
- A fully integrated sawtooth oscillator whose frequency is 500KHz
- Two embedded current limitations circuitries which control the current that flows through the power switch. The Pulse by Pulse Current Limit forces the power switch OFF cycle by cycle if the current reaches an internal threshold, while the Frequency Shifter reduces the switching frequency in order to strongly reduce the duty cycle.
- A transconductance error amplifier.
- A pulse width modulator (PWM) comparator and the relative logic circuitry necessary to drive the internal power.
- An high side driver for the internal P-MOS switch.
- An inhibit block for stand-by operation.
- A circuit to realize the thermal protection function.

Figure 4. Block Diagram

#### 3.1 POWER SUPPLY & VOLTAGE REFERENCE

The internal regulator circuit (shown in Figure 2) consists of a start-up circuit, an internal voltage Preregulator, the Bandgap voltage reference and the Bias block that provides current to all the blocks.

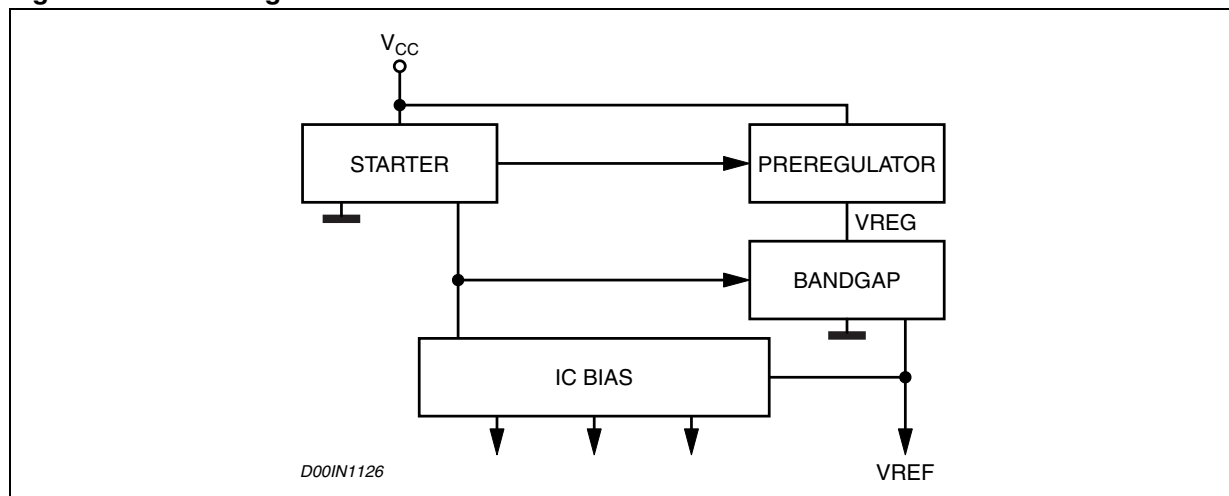

The Starter gives the start-up currents to the whole device when the input voltage goes high and the device is enabled (inhibit pin connected to ground).

The Preregulator block supplies the Bandgap cell with a preregulated voltage  $V_{REG}$  that has a very low supply voltage noise sensitivity.

#### 3.2 VOLTAGES MONITOR

An internal block senses continuously the  $V_{CC}$ ,  $V_{ref}$  and  $V_{bg}$ . If the voltages go higher than their thresholds, the regulator starts to work. There is also an hysteresis on the  $V_{CC}$  (UVLO).

Figure 5. Internal Regulator Circuit

### 3.3 OSCILLATOR & SYNCHRONIZATOR

Figure 6 shows the block diagram of the oscillator circuit.

The Clock Generator provides the switching frequency of the device that is internally fixed at 500KHz. The frequency shifter block acts reducing the switching frequency in case of strong overcurrent or short circuit. The clock signal is then used in the internal logic circuitry and is the input of the Ramp Generator and Synchronizator blocks.

The Ramp Generator circuit provides the sawtooth signal, used to realize the PWM control and the internal voltage feed forward, while the Synchronizator circuit generates the synchronization signal. Infact the device has a synchronization pin that can works both as Master and Slave.

As Master to synchronize external devices to the internal switching frequency.

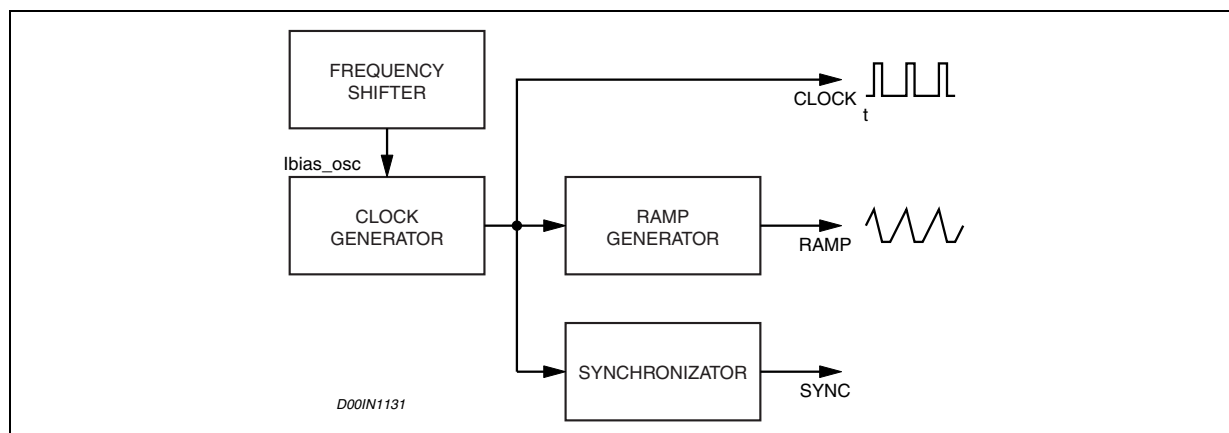

As Slave to synchronize itself by external signal.

In particular, connecting together two devices, the one with the lower switching frequency works as Slave and the other one works as Master.

To synchronize the device, the SYNC pin has to pass from a low level to a level higher than the synchronization threshold with a duty cycle that can vary approximately from 10% to 90%, depending also on the signal frequency and amplitude.

The frequency of the synchronization signal must be at least higher than the internal switching frequency of the device (500KHz).

Figure 6. Oscillator Circuit

### 3.4 CURRENT PROTECTION

The L5970AD has two current limit protections, pulse by pulse and frequency fold back.

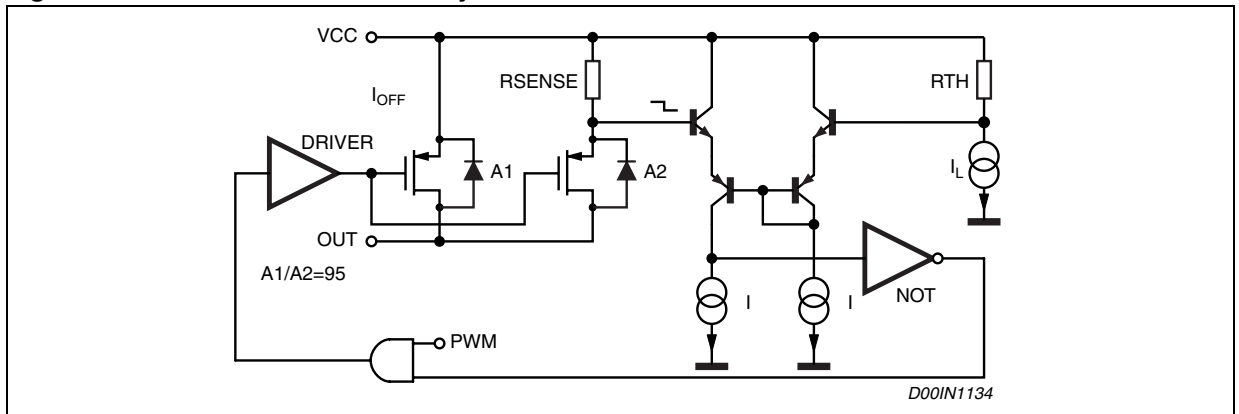

The schematic of the current limitation circuitry for the pulse by pulse protection is shown in figure 7.

The output power PDMOS transistor is split in two parallel PDMOS. The smallest one has a resistor in series,  $R_{SENSE}$ . The current is sensed through  $R_{sense}$  and if reaches the threshold, the mirror is unbalanced and the PDMOS is switched off until the next falling edge of the internal clock pulse.

Due to this reduction of the ON time, the output voltage decreases.

Since the minimum switch ON time (necessary to avoid false overcurrent signal) is not enough to obtain a sufficiently low duty cycle at 500KHz, the output current, in strong overcurrent or short circuit conditions, could increase again. For this reason the switching frequency is also reduced, so keeping the inductor current under its maximum threshold. The Frequency Shifter (see fig. 6) depends on the feedback voltage. As the feedback voltage decreases (due to the reduced duty cycle), the switching frequency decreases too.

**Figure 7. Current Limitation Circuitry**

### 3.5 ERROR AMPLIFIER

The voltage error amplifier is the core of the loop regulation. It is a transconductance operational amplifier whose non inverting input is connected to the internal voltage reference (1.235V), while the inverting input (FB) is connected to the external divider or directly to the output voltage. The output (COMP) is connected to the external compensation network.

The uncompensated error amplifier has the following characteristics:

Transconductance	2300 $\mu$ S
Low frequency gain	65dB
Minimum sink/source voltage	1500 $\mu$ A/300 $\mu$ A
Output voltage swing	0.4V/3.65V
Input bias current	2.5 $\mu$ A

The error amplifier output is compared with the oscillator sawtooth to perform PWM control.

### 3.6 PWM COMPARATOR AND POWER STAGE

This block compares the oscillator sawtooth and the error amplifier output signals generating the PWM signal for the driving stage.

The power stage is a very critical block cause it has to guarantee a correct turn on and turn off of the PDMOS.

### **3.8 THERMAL SHUTDOWN**

The shutdown block generates a signal that turns off the power stage if the temperature of the chip goes higher than a fixed internal threshold (150°C). The sensing element of the chip is very close to the PDMOS area, so ensuring an accurate and fast temperature detection. An hysteresis of approximately 20°C avoids that the devices turns on and off continuously

## **4 Additional Features and Protections**

### **4.1 FEEDBACK DISCONNECTION**

In case of feedback disconnection, the duty cycle increases versus the maximum allowed value, bringing the output voltage close to the input supply. This condition could destroy the load.

To avoid this dangerous condition, the device is turned off if the feedback pin remains floating.

### **4.2 OUTPUT OVERVOLTAGE PROTECTION**

The overvoltage protection, OVP, is realized by using an internal comparator, which input is connected to the feedback, that turns off the power stage when the OVP threshold is reached. This threshold is typically 30% higher than the feedback voltage.

When a voltage divider is requested for adjusting the output voltage (see test application circuit), the OVP intervention will be set at:

$$V_{OVP} = 1.3 \cdot \frac{R_1 + R_2}{R_2} \cdot V_{FB}$$

Where  $R_1$  is the resistor connected between the output voltage and the feedback pin, while  $R_2$  is between the feedback pin and ground.

### **4.3 ZERO LOAD**

Due to the fact that the internal power is a PDMOS, no bootstrap capacitor is required and so, the device works properly also with no load at the output. In this condition it works in burst mode, with random repetition rate of the burst.

## **5 Application Ideas**

L5970AD belongs to L597x family.

Related part numbers are:

- L5970D: 1.5A ( $I_{SW}$ ), 250KHz Step Down DC-DC Converter in SO8
- L5972D: 2A ( $I_{SW}$ ), 250KHz Step Down DC-DC Converter in SO8
- L5973AD: 2A ( $I_{SW}$ ), 500KHz Step Down DC-DC Converter in HSOP8
- L5973D: 2.5A ( $I_{SW}$ ), 250KHz Step Down DC-DC Converter in HSOP8

In case higher current is needed, the nearest DC-DC Converter family is L497x.
