

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

High voltage startup transition-mode PFC

Datasheet – production data

Features

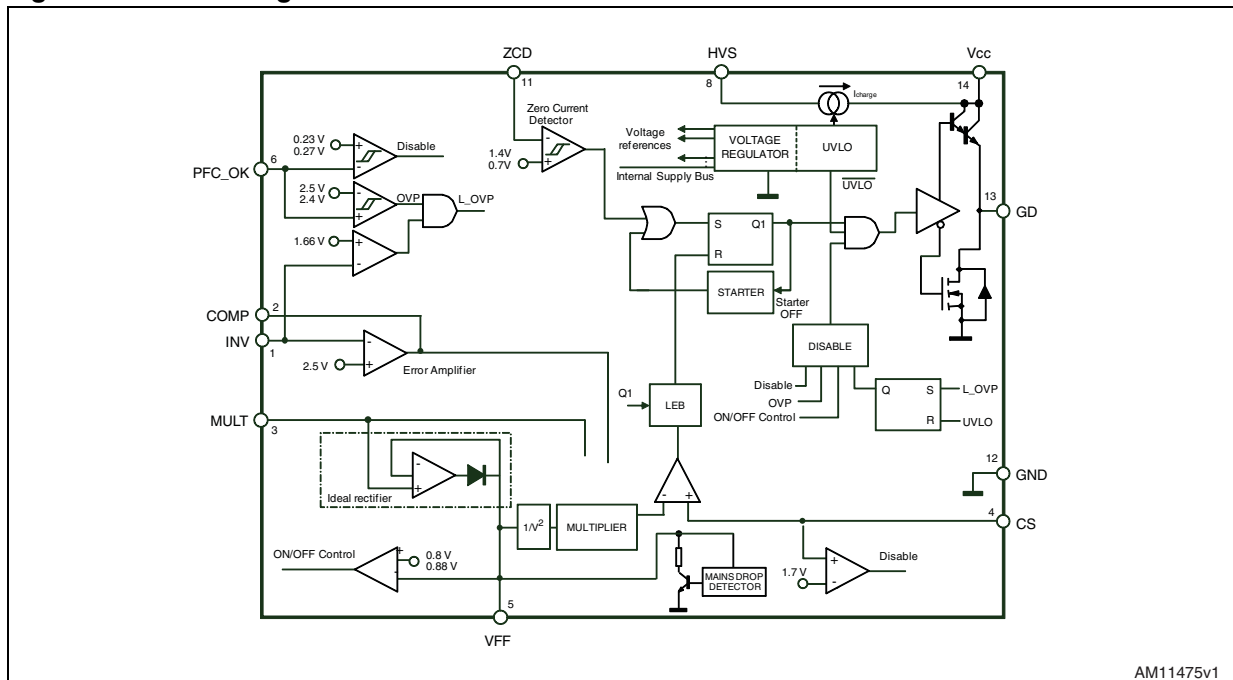

- Onboard 700 V startup source
- Fast “bi-directional” input voltage feedforward ($1/V^2$ correction)
- Accurate adjustable output overvoltage protection
- Protection against feedback loop disconnection (latched shutdown)
- Inductor saturation protection
- AC brownout detection
- Low ($\leq 100 \mu\text{A}$) startup current
- 6 mA max. operating bias current
- 1% (@ $T_J = 25 \text{ }^\circ\text{C}$) internal reference voltage
- -600/+800 mA totem pole gate driver with active pull-down during UVLO
- SO-14 package

Application

- PFC pre-regulators for:
 - High-end AC-DC adapter/charger
 - IEC61000-3-2 or JEITA-MITI compliant SMPS, in excess of 400 W
 - SMPS for LED luminaires

1 Description

The L6564H is a current-mode PFC controller operating in transition mode (TM) which embeds the same features existing in the L6564 with the addition of a high voltage startup source. These functions make the IC especially suitable for applications that must be compliant with energy saving regulations and where the PFC preregulator works as the master stage.

The highly linear multiplier, along with a special correction circuit that reduces crossover distortion of the mains current, allows wide-range-mains operation with an extremely low THD even over a large load range.

The output voltage is controlled by means of a voltage-mode error amplifier and an accurate (1% @ $T_J = 25\text{ °C}$) internal voltage reference. The loop stability is optimized by the voltage feedforward function ($1/V^2$ correction), which, in this IC, uses a proprietary technique that also considerably improves line transient response in the case of both mains drops and surges ("bi-directional").

In addition to overvoltage protection able to control the output voltage during transient conditions, the IC also provides protection against feedback loop failures or erroneous settings. Other onboard protection functions allow brownout conditions and boost inductor saturation to be safely handled.

The totem pole output stage, capable of a 600 mA source and 800 mA sink current, is suitable for a high power MOSFET or IGBT drive. This, combined with the other features and the possibility to operate with ST's proprietary fixed-off-time control, makes the device an excellent solution for SMPS up to 400 W that requires compliance with EN61000-3-2 and JEITA-MITI standards.

2 Maximum ratings

2.1 Absolute maximum ratings

Table 1. Absolute maximum ratings

Symbol	Pin	Parameter	Value	Unit
V_{HVS}	8	Voltage range (referred to ground)	-0.3 to 700	V
I_{HVS}	8	Output current	Self-limited	I_{HVS}
V_{CC}	14	IC supply voltage ($I_{CC} \leq 20$ mA)	Self-limited	V
---	1, 3, 6	Max. pin voltage ($I_{pin} \leq 1$ mA)	Self-limited	V
---	2, 4, 5	Analog inputs and outputs	-0.3 to 8	V
I_{ZCD}	11	Zero current detector max. current	-10 (source) 10 (sink)	mA
VFF pin	5	Maximum withstanding voltage range test condition: CDF-AEC-Q100-002 "human body model" acceptance criteria: "normal performance"	+/- 1750	V
Other pins	1 to 4 6, 8, 11 to 14		+/- 2000	V

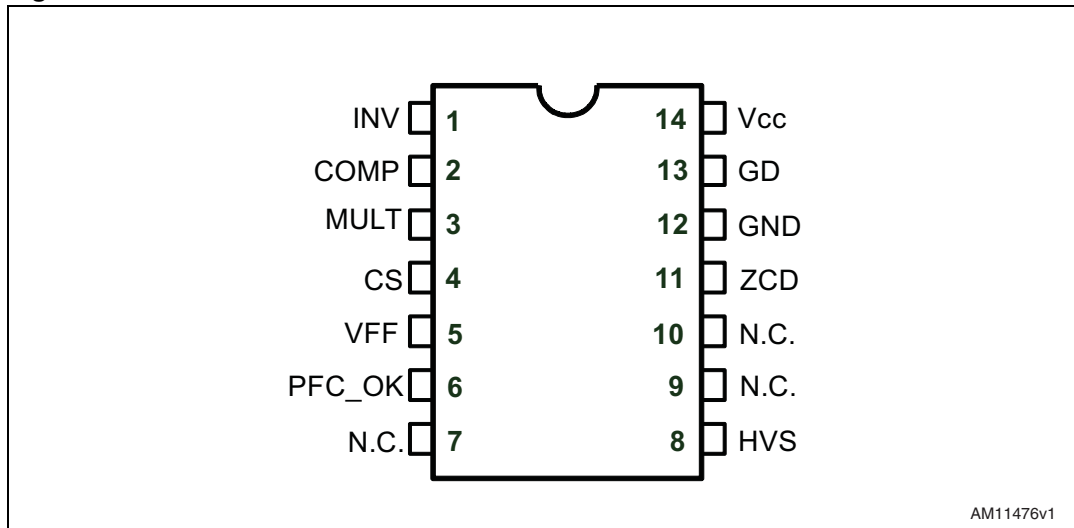

2.2 Thermal data

Table 2. Thermal data

Symbol	Parameter	Value	Unit
R_{thJA}	Max. thermal resistance, junction-to-ambient	120	°C/W
P_{tot}	Power dissipation @ $T_A = 50$ °C	0.75	W
T_J	Junction temperature operating range	-40 to 150	°C
T_{stg}	Storage temperature	-55 to 150	°C

3 Pin connection

Figure 2. Pin connection

AM11476v1

Table 3. Pin description

n°	Name	Function
1	INV	Inverting input of the error amplifier. The information on the output voltage of the PFC pre-regulator is fed into the pin through a resistor divider. The pin normally features high impedance.
2	COMP	Output of the error amplifier. A compensation network is placed between this pin and INV (pin 1) to achieve stability of the voltage control loop and ensure high power factor and low THD. To avoid an uncontrolled rise of the output voltage at zero load, when the voltage on the pin falls below 2.4 V the gate driver output is inhibited (burst-mode operation).
3	MULT	Main input to the multiplier. This pin is connected to the rectified mains voltage via a resistor divider and provides the sinusoidal reference to the current loop. The voltage on this pin is used also to derive the information on the RMS mains voltage.
4	CS	Input to the PWM comparator. The current flowing in the MOSFET is sensed through a resistor, the resulting voltage is applied to this pin and compared with an internal reference to determine MOSFET turn-off. A second comparison level at 1.7 V detects abnormal currents (e.g. due to boost inductor saturation) and, on this occurrence, activates a safety procedure that temporarily stops the converter and limits the stress of the power components.
5	VFF	Second input to the multiplier for $1/V^2$ function. A capacitor and a parallel resistor must be connected from the pin to GND. They complete the internal peak-holding circuit that derives the information on the RMS mains voltage. The voltage at this pin, a DC level equal to the peak voltage on the MULT pin (3), compensates the control loop gain dependence on the mains voltage. Never connect the pin directly to GND but with a resistor ranging from 100 K Ω (minimum) to 2 M Ω (maximum).

Table 3. Pin description (continued)

n°	Name	Function
6	PFC_OK	PFC pre-regulator output voltage monitoring/disable function. This pin senses the output voltage of the PFC pre-regulator through a resistor divider and is used for protection purposes. If the voltage on the pin exceeds 2.5 V, the IC stops switching and restarts as the voltage on the pin falls below 2.4 V. However, if at the same time the voltage of the INV pin falls below 1.66 V, a feedback failure is assumed. In this case the device is latched off. Normal operation can be resumed only by cycling V_{CC} , bringing its value lower than 6 V before moving up to the turn-on threshold. If the voltage on this pin is brought below 0.23 V, the IC is shut down. To restart the IC the voltage on the pin must go above 0.27 V. This can be used as a remote on/off control input.
7	N.C.	Not internally connected. Provision for clearance on the PCB to meet safety requirements.
8	HVS	High voltage startup. The pin, able to withstand 700 V, is to be tied directly to the rectified mains voltage. A 1 mA internal current source charges the capacitor connected between the V_{CC} pin (14) and the GND pin (12) until the voltage on the V_{CC} pin reaches the startup threshold, it is then shut down. Normally, the generator is re-enabled when the V_{CC} voltage falls below 6 V to ensure a low power throughput during short-circuit. Otherwise, when a latched protection is tripped the generator is re-enabled as V_{CC} reaches the UVLO threshold to keep the latch supplied.
9	N.C.	Not internally connected. Provision for clearance on the PCB to meet safety requirements.
10	N.C.	Not internally connected. Provision for clearance on the PCB to meet safety requirements.
11	ZCD	Boost inductor demagnetization sensing input for transition-mode operation. A negative-going edge triggers MOSFET turn-on.
12	GND	Ground. Current return for both the signal part of the IC and the gate driver.
13	GD	Gate driver output. The totem pole output stage is able to drive Power MOSFETs and IGBTs with a peak current of 600 mA source and 800 mA sink. The high level voltage of this pin is clamped at about 12 V to avoid excessive gate voltages.
14	V_{CC}	Supply voltage of both the signal part of the IC and the gate driver. Sometimes a small bypass capacitor (0.1 μ F typ.) to GND might be useful to get a clean bias voltage for the signal part of the IC.

Figure 3. Typical system block diagram

4 Electrical characteristics

($T_J = -25$ to 125 °C, $V_{CC} = 12$ V, $C_O = 1$ nF between pin GD and GND, $C_{FF} = 1$ μF and $R_{FF} = 1$ MΩ between pin VFF and GND; unless otherwise specified.)

6 Application information

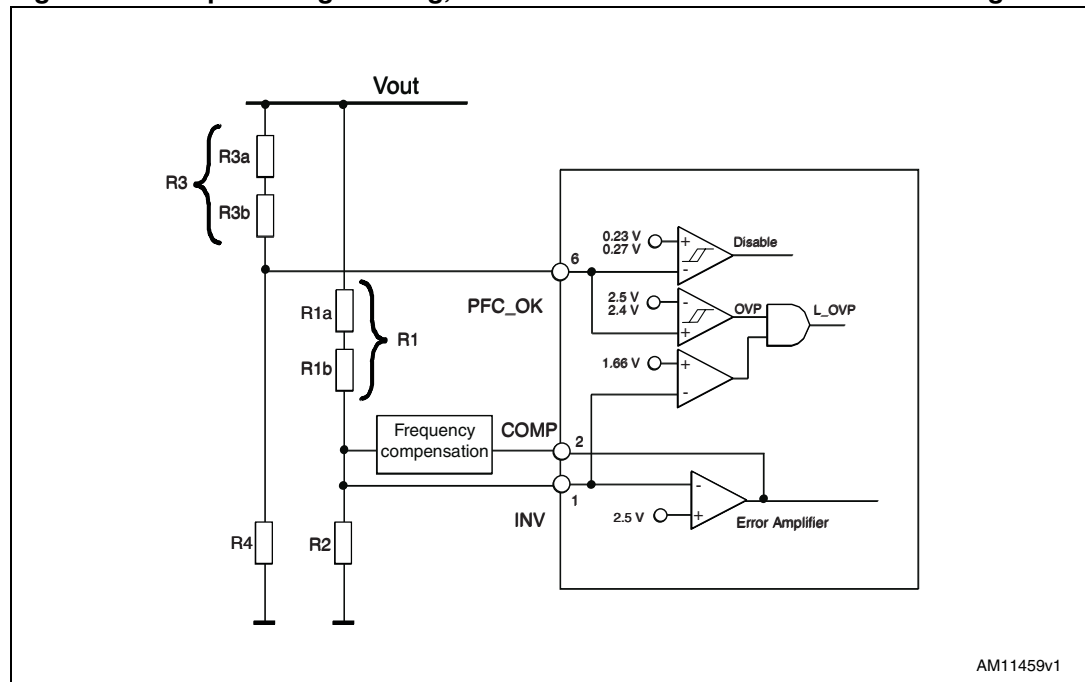

6.1 Overvoltage protection

Normally, the voltage control loop keeps the output voltage V_o of the PFC pre-regulator close to its nominal value, set by the ratio of the resistors R1 and R2 of the output divider. A pin of the device (PFC_OK) has been dedicated to monitor the output voltage with a separate resistor divider (R3 high, R4 low, see [Figure 31](#)). This divider is selected so that the voltage at the pin reaches 2.5 V if the output voltage exceeds a preset value, usually larger than the maximum V_o that can be expected.

Example 1: $V_o = 400\text{ V}$, $V_{OX} = 434\text{ V}$. Select: $R3 = 8.8\text{ M}\Omega$; then: $R4 = 8.8\text{ M}\Omega \cdot 2.5 / (434 - 2.5) = 51\text{ k}\Omega$

When this function is triggered, the gate drive activity is immediately stopped until the voltage on the PFC_OK pin drops below 2.4 V. Note that R1, R2, R3 and R4 can be selected without any constraints. The unique criterion is that both dividers must sink a current from the output bus which needs to be significantly higher than the bias current of both INV and PFC_OK pins.

Figure 31. Output voltage setting, OVP and FFP functions: internal block diagram

6.2 Feedback failure protection (FFP)

The OVP function described above handles “normal” overvoltage conditions, i.e. those resulting from an abrupt load/line change or occurring at startup. If the overvoltage is generated by a feedback disconnection, for instance when the upper resistor of the output divider (R1) fails to open, the comparator detects the voltage at the INV pin. If the voltage is lower than 1.66 V and the OVP is active, the FFP is triggered, the gate drive activity is

immediately stopped, the device is shut down, its quiescent consumption is reduced below 180 μ A, and the condition is latched as long as the supply voltage of the IC is above the UVLO threshold. To restart the system it is necessary to recycle the input power, so that the V_{CC} voltage of the L6564H goes below 6 V.

The PFC_OK pin doubles its function as a not-latched IC 'disable': a voltage below 0.23 V shuts down the IC, reducing its consumption below 2 mA. To restart the IC simply let the voltage at the pin go above 0.27 V.

Note that these functions offer complete protection against not only feedback loop failures or erroneous settings, but also against a failure of the protection itself. Either resistor of the PFC_OK voltage divider in a short condition or open, or the PFC_OK pin left floating, results in shutting down the IC and stopping the pre-regulator.

6.3 Voltage feedforward

The power stage gain of PFC pre-regulators varies with the square of the RMS input voltage. So does the crossover frequency f_c of the overall open-loop gain because the gain has a single pole characteristic. This leads to a large trade-off in the design.

For example, setting the gain of the error amplifier to get $f_c = 20$ Hz @ 264 Vac means having $f_c \approx 4$ Hz @ 88 Vac, resulting in sluggish control dynamics. Additionally, the slow control loop causes large transient current flow during rapid line or load changes that are limited by the dynamics of the multiplier output. This limit is considered when selecting the sense resistor to let the full load power pass under minimum line voltage conditions, with some margin. But a fixed current limit allows excessive power input at high line, whereas a fixed power limit requires the current limit to vary inversely with the line voltage.

Voltage feedforward can compensate for the gain variation with the line voltage and allow the minimizing of all the issues mentioned above. It consists of deriving a voltage proportional to the input RMS voltage, feeding this voltage into a squarer/divider circuit ($1/V^2$ corrector) and providing the resulting signal to the multiplier that generates the current reference for the inner current control loop (see [Figure 32](#)).

Figure 32. Voltage feedforward: squarer/divider ($1/V^2$) block diagram and transfer characteristics

In this way a change of the line voltage causes an inversely proportional change of the half sine amplitude at the output of the multiplier (if the line voltage doubles the amplitude of the multiplier output is halved and vice versa) so that the current reference is adapted to the new operating conditions with (ideally) no need for invoking the slow dynamics of the error amplifier. Additionally, the loop gain is constant throughout the input voltage range, which significantly improves dynamic behavior at low line and simplifies loop design.

Actually, deriving a voltage proportional to the RMS line voltage implies a form of integration, which has its own time constant. If it is too small, the voltage generated is affected by a considerable amount of ripple at twice the mains frequency which causes distortion of the current reference (resulting in high HD and poor PF); if it is too large there is a considerable delay in setting the right amount of feedforward, resulting in excessive overshoot and undershoot of the pre-regulator output voltage in response to large line voltage changes. Clearly a trade-off was required.

The L6564H realizes a new voltage feedforward that, with a technique that makes use of just two external parts, strongly minimizes this time constant trade-off issue whichever voltage change occurs on the mains, both surges and drops. A capacitor C_{FF} and a resistor R_{FF} both connected from the VFF pin (#5) to ground, complete an internal peak-holding circuit that provides a DC voltage equal to the peak of the rectified sine wave applied on the MULT pin (#3). In this way, in the case of sudden line voltage rise, C_{FF} is rapidly charged through the low impedance of the internal diode; in the case of line voltage drop, an internal “mains drop” detector enables a low impedance switch which suddenly discharges C_{FF} avoiding a long settling time before reaching the new voltage level. The discharge of C_{FF} is stopped as its voltage equals the voltage on the MULT pin or if the voltage on the VFF pin falls below 0.88 V, to prevent the “brownout protection” function from being improperly activated (see [Section 6.6: Power management/housekeeping functions](#)).

As a result of the VFF pin functionality, an acceptably low steady-state ripple and low current distortion can be achieved with a limited undershoot or overshoot on the pre-regulator output.

The twice-mains-frequency ($2 \cdot f_L$) ripple appearing across C_{FF} is triangular with a peak-to-peak amplitude that, with good approximation, is given by:

$$\Delta V_{FF} = \frac{2 V_{MULTpk}}{1 + 4f_L R_{FF} C_{FF}}$$

where f_L is the line frequency. The amount of 3rd harmonic distortion introduced by this ripple, related to the amplitude of its $2 \cdot f_L$ component, is:

$$D_3\% = \frac{100}{2\pi f_L R_{FF} C_{FF}}$$

[Figure 33](#) shows a diagram that helps in choosing the time constant $R_{FF} \cdot C_{FF}$ based on the amount of maximum desired 3rd harmonic distortion. Note that there is a minimum value for the time constant $R_{FF} \times C_{FF}$ below which improper activation of the VFF fast discharge may occur. In fact, the twice-mains frequency ripple across C_{FF} under steady-state conditions must be lower than the minimum line drop detection threshold ($DV_{VFF_min} = 40$ mV). Therefore: must be lower than the minimum line drop detection threshold ($\Delta V_{FF_min} = 40$ mV).

So:

$$R_{FF} \cdot C_{FF} > \frac{2 \frac{V_{MULTpk_max}}{\Delta V_{VFF_min}} - 1}{4 f_{L_min}}$$

Always connect R_{FF} and C_{FF} to the pin, the IC does not work properly if the pin is either left floating or connected directly to ground.

6.4 THD optimizer circuit

The L6564H is provided with a special circuit that reduces the conduction dead-angle occurring at the AC input current near the zero-crossings of the line voltage (crossover distortion). In this way the THD (total harmonic distortion) of the current is considerably reduced.

A major cause of this distortion is the inability of the system to transfer energy effectively when the instantaneous line voltage is very low. This effect is magnified by the high-frequency filter capacitor placed after the bridge rectifier, which retains some residual voltage that causes the diodes of the bridge rectifier to be reverse-biased and the input current flow to temporarily stop.

To overcome this issue the device forces the PFC pre-regulator to process more energy near the line voltage zero-crossings as compared to that commanded by the control loop. This results in both minimizing the time interval where energy transfer is lacking and fully discharging the high-frequency filter capacitor after the bridge.

Figure 34 shows the internal block diagram of the THD optimizer circuit.

Figure 34. THD optimizer circuit

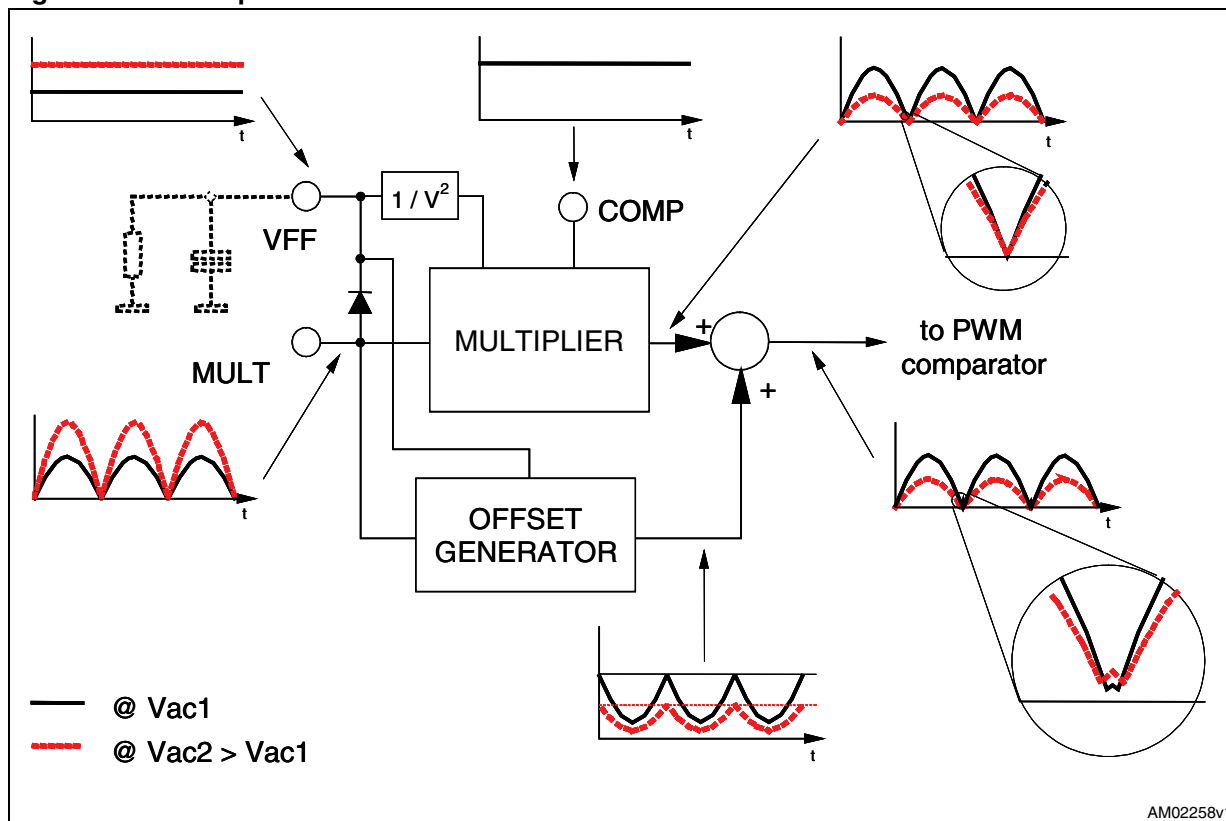

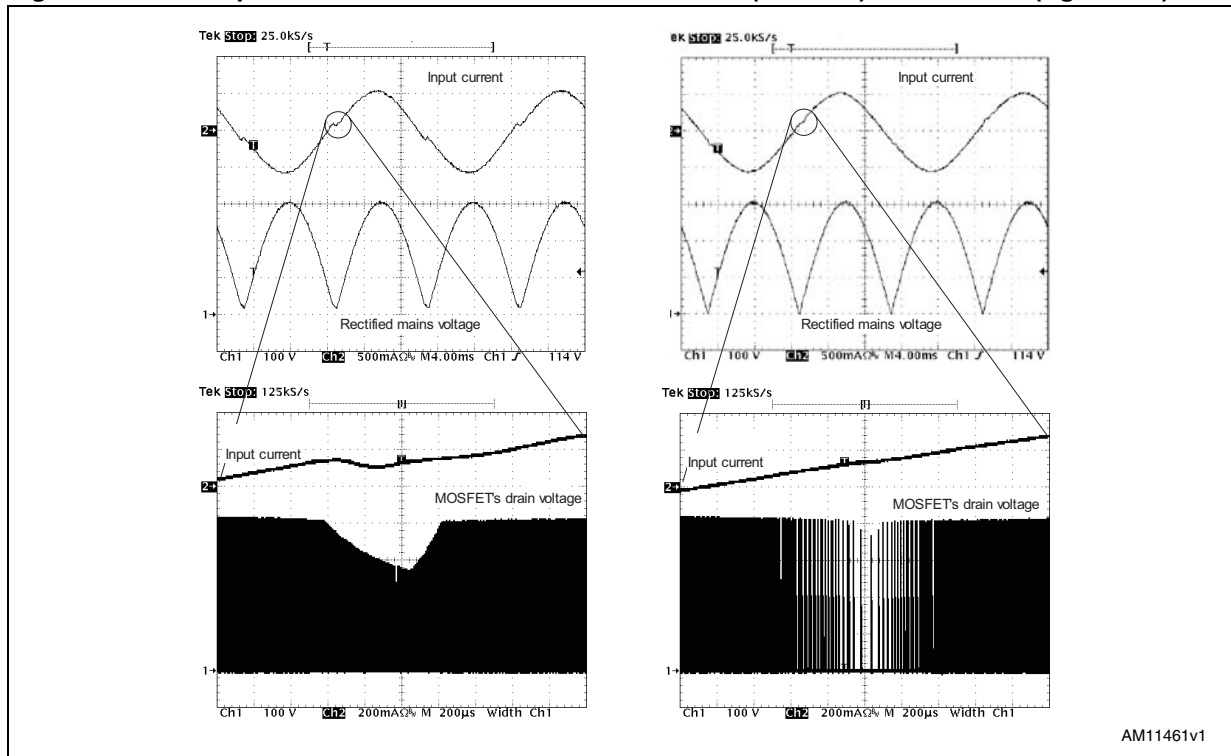

Figure 35. THD optimization: standard TM PFC controller (left side) and L6564H (right side)

Essentially, the circuit artificially increases the ON-time of the power switch with a positive offset added to the output of the multiplier in the proximity of the line voltage zero-crossings. This offset is reduced as the instantaneous line voltage increases, so that it becomes negligible as the line voltage moves toward the top of the sinusoid. Furthermore, the offset is modulated by the voltage on the VFF pin (see [Section 6.3](#)) so as to have little offset at low line, where energy transfer at zero crossings is typically quite good, and a larger offset at high line where the energy transfer worsens.

The effect of the circuit is shown in [Figure 35](#), where the key waveforms of a standard TM PFC controller are compared to those of this chip.

To take maximum benefit from the THD optimizer circuit, the high-frequency filter capacitor after the bridge rectifier should be minimized, compatibly with EMI filtering needs. A large capacitance, in fact, introduces a conduction dead-angle of the AC input current in itself - even with an ideal energy transfer by the PFC pre-regulator - therefore reducing the effectiveness of the optimizer circuit.

6.5 Inductor saturation detection

The boost inductor's hard saturation may be a fatal event for a PFC pre-regulator: the current up-slope becomes so large (50-100 times steeper, see [Figure 36](#)) that during the current sense propagation delay the current may reach abnormally high values. The voltage drop caused by this abnormal current on the sense resistor reduces the gate-to-source voltage, so that the MOSFET may work in the active region and dissipate a huge amount of power, which leads to a catastrophic failure after few switching cycles.

However, in some applications such as AC-DC adapters, where the PFC pre-regulator is turned off at light load for energy saving reasons, even a well-designed boost inductor may

occasionally slightly saturate when the PFC stage is restarted because of a larger load demand. This happens when the restart occurs at an unfavorable line voltage phase, i.e. when the output voltage is significantly below the rectified peak voltage. As a result, in the boost inductor, the inrush current coming from the bridge rectifier adds to the switched current and, furthermore, there is little or no voltage available for demagnetization.

To cope with a saturated inductor, the L6564H is provided with a second comparator on the current sense pin (CS, pin 4) that stops the IC if the voltage, normally limited within 1.1 V, exceeds 1.7 V. After that, the IC attempts to restart through the internal starter circuitry; the starter repetition time is twice the nominal value to guarantee lower stress for the inductor and boost diode. Hence, system safety is considerably increased.

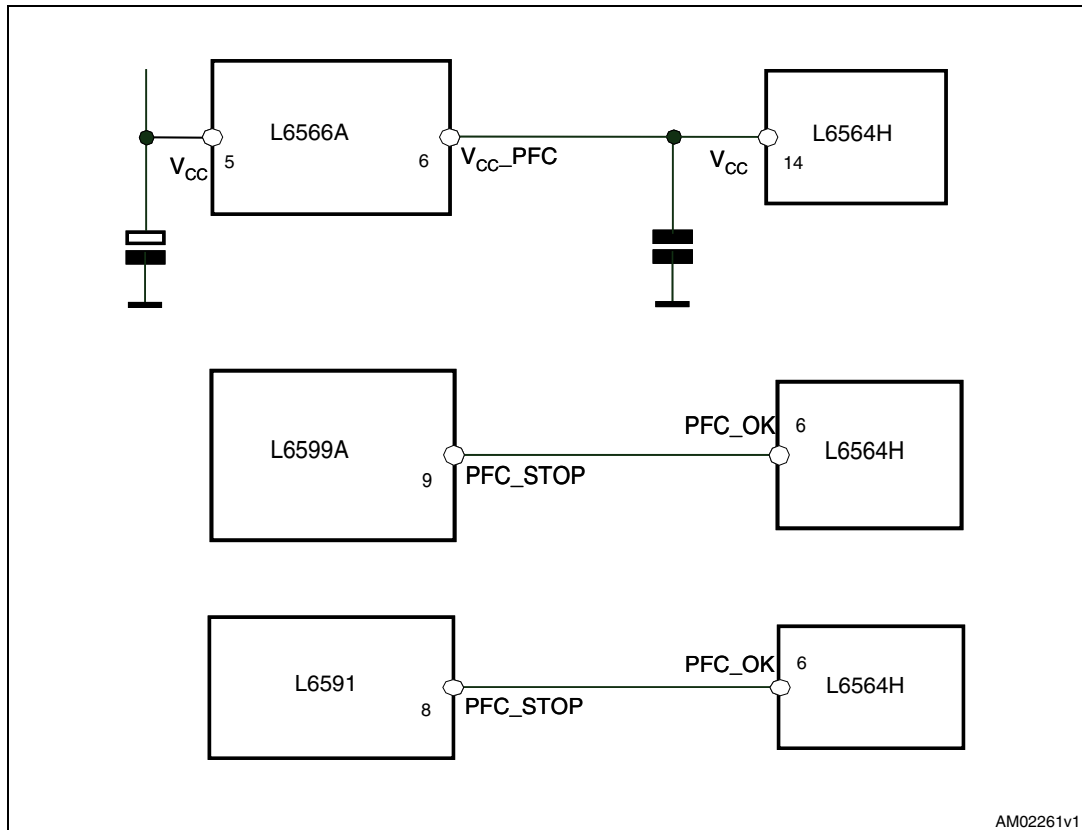

Figure 36. Effect of boost inductor saturation on the MOSFET current and detection method

6.6 Power management/housekeeping functions

A communication line with the control IC of the cascaded DC-DC converter can be established via the disable function included in the PFC_OK pin (see [Section 6.2](#) for more details). This line is typically used to allow the PWM controller of the cascaded DC-DC converter to shut down the L6564H in case of light load and to minimize the no-load input consumption. Should the residual consumption of the chip be an issue, it is also possible to cut down the supply voltage. Interface circuits are shown in [Figure 37](#). Needless to say, this operation assumes that the cascaded DC-DC converter stage works as the master and the PFC stage as the slave or, in other words, that the DC-DC stage starts first, it powers both controllers and enables/disables the operation of the PFC stage.

Figure 37. Interface circuits that let the DC-DC converter's controller IC disable the L6564H

Another function available is the brownout protection which is basically a not-latched shutdown function that is activated when a condition of mains undervoltage is detected. This condition may cause overheating of the primary power section due to an excess of RMS current. Brownout can also cause the PFC pre-regulator to function in open loop and this may be dangerous to the PFC stage itself and the downstream converter, should the input voltage return abruptly to its rated value. Another problem is the spurious restarts that may occur during converter power-down and that cause the output voltage of the converter not to decay to zero monotonically. For these reasons it is usually preferable to shut down the unit in case of brownout. The brownout threshold is internally fixed at 0.8 V and is sensed on the VFF pin (#5) during the voltage falling and an 80 mV threshold hysteresis prevents rebounding at input voltage turn-off. In [Table 5](#) it is possible to find a summary of all of the above mentioned working conditions that cause the device to stop operating.
