## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

LT1249
Power Factor Controller

## feATURES

- Standard 8-Pin Packages
- High Power Factor Over Wide Load Range with Line Current Averaging
- International Operation Without Switches
- Instantaneous Overvoltage Protection
- Minimal Line Current Dead Zone
- Typical 250رA Start-Up Supply Current
- Rejects Line Switching Noise
- Synchronization Capability
- Low Quiescent Current: 9mA
- Fast 1.5A Peak Current Gate Driver

## APPLICATIONS

- Universal Power Factor Corrected Power Supplies
- Preregulators up to 1500W
$\overline{\boldsymbol{\wedge}}$, LTC and LT are registered trademarks of Linear Technology Corporation.

## DESCRIPTIOn

The 8-pin $\mathrm{LT}^{\circledR} 1249$ provides active power factor correction for universal offline power systems with very few external parts. By using fixed high frequency PWM current averaging without the need for slope compensation, the LT1249 achieves far lower line current distortion, with a smaller magnetic element than systems that use either peak current detection or zero current switching approach, in both continuous and discontinuous modes of operation.

The LT1249 uses a multiplier containing a square gain function from the voltage amplifier to reduce the AC gain at light output load and thus maintains low line current distortion and high system stability. The LT1249 also provides filtering capability to reject line switching noise which can cause instability when fed into the multiplier. Line current dead zone is minimized with low bias voltage at the current input to the multiplier.

The LT1249 provides many protection features including peak current limiting and overvoltage protection. The switching frequency is internally set at 100 kHz .
While the LT1249 simplifies PFC design with minimal parts count, the LT1248 provides flexibilities in switching frequency, overvoltage and current limit.

## PIn functions

GND (Pin 1): Ground.
CA $_{\text {OUt }}$ (Pin 2): This is the output of the current amplifier that senses and forces the line current to follow the reference signal that comes from the multiplier by commanding the pulse width modulator. When CAOut is low, the modulator has zero duty cycle.
$\mathrm{M}_{\text {Out }}$ (Pin 3): The multiplier current goes out of this pin through the 4 k resistor $\mathrm{R}_{\text {Mout }}$. The voltage developed across $\mathrm{R}_{\text {mout }}$ is the reference voltage of the current loop and it is limited to 1.1 V . The noninverting input of the current amplifier is also tied to $\mathrm{R}_{\text {MOUT. }}$ In operation, $\mathrm{M}_{\text {OUT }}$
is normally at negative potential and only AC signals appear at the noninverting input of the current amplifier.
$\mathrm{I}_{\mathrm{AC}}$ (Pin 4): This is the AC line voltage sensing input to the multiplier. It is a current input that is biased at 2 V to minimize the crossover dead zone caused by low line voltage. A 32k resistor is in series with the current input, so that a small external capacitor can be used to filter out the switching noise from the high impedance lines.
VA Out $_{\text {(Pin } 5 \text { ): This is the output of the voltage error }}$ amplifier. The output is clamped at 12V. When the output goes below 1.5 V , the multiplier output current is zero.

## PIn functions

$\mathbf{V}_{\text {SENSE }}($ Pin 6$)$ : This is the inverting input to the voltage amplifier.
$V_{\text {CC }}$ (Pin 7): This is the supply of the chip. The LT1249 has a very fast gate driver required to fast charge high power MOSFET gate capacitance. High current spikes occur during charging. For good supply bypass, a $0.1 \mu \mathrm{~F}$ ceramic
capacitor in parallel with a low ESR electrolytic capacitor, $56 \mu \mathrm{~F}$ or higher is required in close proximity to IC GND.
GTDR (Pin 8): The MOSFET gate driver is a 1.5A fast totem pole output. It is clamped at 15 V . Capacitive loads like MOSFET gates may cause overshoot. A gate series resistor of at least $5 \Omega$ will prevent the overshoot.

## APPLLCATIONS Information

## Error Amplifier

The error amplifier has a 100dB DC gain and 1.5MHz unitygain frequency. It is internally clamped at 12 V . The noninverting input is tied to the 7.5 V reference.

## Current Amplifier

The multiplier output current $\mathrm{I}_{\mathrm{M}}$ flows out of the $\mathrm{M}_{\text {OUT }}$ pin through the 4 k resistor $\mathrm{R}_{\text {MOUT }}$ and develops the reference signal to the current loop that is controlled by the current amplifier. Current gain is the ratio of $\mathrm{R}_{\text {MOUT }}$ to line current sense resistor. The current amplifier is a transconductance amplifier. Typical $g_{m}$ is $320 \mu \mathrm{mho}$ and gain is 60 dB with no load. The inverting input is internally tied to GND. The noninverting input is tied to the multiplier output. The output is internally clamped at 8 V . Output resistance is about 4M; DC loading should be avoided because it will lower the gain and introduce offset voltage at the inputs which becomes a false reference signal to the current loop and can distort line current. Note that in the current averaging operation, high gain at twice the line frequency is necessary to minimize line current distortion. Because CA ${ }_{\text {OUt }}$ may need to swing 5V over one line cycle at high line condition, 11 mV will be present at the inputs of the current amplifier if gain is rolled off to 450 at 120 Hz ( 1 nF in series with 10k at CA $A_{\text {OUT }}$ ). At light load, when $\left(\mathrm{I}_{\mathrm{M}}\right)\left(\mathrm{R}_{\text {MOUT }}\right)$ can be less than 100 mV , lower gain will distort the current loop reference signal and line current. If signal gain at the 100 kHz switching frequency is too high, the system behaves more like a current mode system and can cause subharmonic oscillation. Therefore, the current amplifier should be compensated to have a gain of less than 15 at 100 kHz and more than 300 at 120 Hz .

## Multiplier

The multiplier is a current multiplier with high noise immunity in a high power switching environment. The current gain is:

$$
\begin{aligned}
& I_{M}=\left(I_{A C}\right)\left(I_{E A}{ }^{2}\right) /(200 \mu A)^{2}, \text { and } \\
& I_{E A}=\left(V A_{O U T}-1.5 V\right) / 25 \mathrm{k}
\end{aligned}
$$

With a square function, because of the lower gain at light power load, system stability is maintained and line current distortion caused by the AC ripple fed back to the error amplifier is minimized. Note that switching ripple on the high impedance lines could get into the multiplier from the $l_{\text {AC }}$ pin and cause instability. The LT1249 provides an internal 25 k resistor in series with the low impedance multiplier current input so that only a capacitor from the $I_{A C}$ pin to GND is needed to filter out the noise. Maximum multiplier output current is limited to $250 \mu \mathrm{~A}$. Figure 1 shows the multiplier transfer curves.

Figure 1. Multiplier Current $I_{M}$ vs $I_{A C}$ and $V A_{\text {OUT }}$

## APPLICATIONS INFORMATION

## Line Current Limiting

Maximum voltage across $\mathrm{R}_{\text {MOUT }}$ is internally limited to 1.1 V . Therefore, line current limit is 1.1 V divided by the sense resistor $R_{S}$. With a $0.2 \Omega$ sense resistor $R_{S}$ line current limit is 5.5 A . As a general rule, $\mathrm{R}_{\mathrm{S}}$ is chosen according

$$
R_{S}=\frac{\left(l_{\text {M(MAX) }}\right)\left(\mathrm{R}_{\text {MOUT }}\right)\left(\mathrm{V}_{\text {LINE(MIIN })}\right)}{\left.\mathrm{K}(1.414) \mathrm{POUT}_{\text {(MAX }}\right)}
$$

where $\mathrm{P}_{\text {OUT(MAX) }}$ is the maximum power output and K is usually between 1.1 and 1.3 depending on efficiency and resistor tolerance. When the output is overloaded and line current reaches limit, output voltage $\mathrm{V}_{\text {OUT }}$ will drop to keep line current constant. System stability is still maintained by the current loop which is controlled by the current amplifier. Further load current increase results in further $V_{\text {Out }}$ drop and clipping of the line current, which degrades power factor.

## Synchronization

The LT1249 can be externally synchronized in a frequency range of 127 kHz to 160 kHz . Figure 2 shows the synchronizing circuit. Synchronizing occurs when $\mathrm{CA}_{\text {Out }}$ pin is pulled below 0.5 V with an external transistor and a Schottky diode. The Schottky diode and the 10k pull-up resistor are necessary for the required fast slewing back up to the normal operating voltage on CA OUt after the transistor is turned off. Positive slewing on $\mathrm{CA}_{\text {out }}$ should be faster than the oscillator ramp rate of $0.5 \mathrm{~V} / \mu \mathrm{s}$.
The width of the synchronizing pulse should be under 60 ns . The synchronizing pulses introduce an offset voltage on the current amplifier inputs, according to:

ts = pulse width
fs = pulse frequency
$I_{C}=$ CA $_{\text {OUT }}$ source current $(\approx 150 \mu \mathrm{~A})$
$\mathrm{V}_{\mathrm{C}}=$ CA $_{\text {OUT }}$ operating voltage ( 1.8 V to 6.8 V )
R2 = resistorfor the midfrequency "zero" in the current loop $\mathrm{g}_{\mathrm{m}}=$ current amplifier transconductance $(\approx 320 \mu \mathrm{mho}$ )

With ts $=30 \mathrm{~ns}, \mathrm{fs}=130 \mathrm{kHz}, \mathrm{V}_{\mathrm{C}}=3 \mathrm{~V}$ and $\mathrm{R} 2=10 \mathrm{k}$, offset voltage shift is $\approx 5 \mathrm{mV}$. Note that this offset voltage will add slight distortion to line current at light load.

Figure 2. Synchronizing the LT1249

## Overvoltage Protection

In Figure 3, R1 and R2 set the regulator output DC level: $V_{\text {OUT }}=V_{\text {REF }}[(R 1+R 2) / R 2]$. With $R 1=1 \mathrm{M}$ and $R 2=20 \mathrm{k}$, $V_{\text {OUt }}$ is 382 V .
Because of the slow loop response necessary for power factor correction, output overshoot can occur with sudden load removal or reduction. To protect the power components and output load, the LT1249 voltage error amplifier senses the output voltage and quickly shuts off the current switch when overvoltage occurs. When overshoot occurs on $V_{\text {OUt }}$, the overcurrent from R1 will go through VA Out $^{\text {R }}$ because amplifier feedback keeps $\mathrm{V}_{\text {SENSE }}$ locked at 7.5 V . When this overcurrent reaches $44 \mu \mathrm{~A}$ amplifier sinking limit, the amplifier loses feedback and its output snaps low to turn the multiplier off.

Overvoltage trip level: $\Delta \mathrm{V}_{\text {OUT }}=(44 \mu \mathrm{~A})(\mathrm{R} 1)$

Figure 3. Overvoltage Protection

## APPLICATIONS INFORMATION

The Figure 3 circuit therefore has 382 V on $\mathrm{V}_{\text {OUt }}$, and an overvoltage level $=\left(V_{\text {OUT }}+44 \mathrm{~V}\right)$, or 426 V . With a $22 \mu \mathrm{~A}$ hysteresis, $\mathrm{V}_{\text {OUT }}$ then has to drop 22 V to 404 V before feedback recovers and the switch turns back on.
$\mathrm{M}_{\text {OUt }}$ is a high impedance current output. In the current loop, offset line current is determined by multiplier offset current and input offset voltage of the current amplifier. A negative 4 mV current amplifier $\mathrm{V}_{0 S}$ translates into 20 mA line current and 5 W input power for 250 V line if $0.2 \Omega$ sense resistor is used. Under no load or when the load power is less than this offset input power, $V_{\text {OUT }}$ would slowly charge up to an overvoltage state because the overvoltage comparator can only reduce multiplier output current to zero. This does not guarantee zero output current if the current amplifier has offset. To regulate $\mathrm{V}_{\text {OUT }}$ under this condition, the amplifier M1 (see Block Diagram), becomes active in the current loop when VAout goes down to 1 V. The M1 can put out up to $15 \mu \mathrm{~A}$ to the 4 k resistor at the inverting input to cancel the current amplifier negative $\mathrm{V}_{0 S}$ and keep $\mathrm{V}_{\text {OUT }}$ error to within 2V.

## Undervoltage Lockout

The LT1249 turns on when $V_{\text {CC }}$ is higher than 16 V and remains on until $\mathrm{V}_{\text {CC }}$ falls below 10 V , whereupon the chip enters the lockout state. In the lockout state, the LT1249 only draws $250 \mu \mathrm{~A}$, the oscillator is off, the $\mathrm{V}_{\text {REF }}$ and the GTDR pins remain low to keep the power MOSFET off.

## Start-Up and Supply Voltage

The LT1249 draws only $250 \mu$ A before the chip starts at 16 V on $\mathrm{V}_{\text {CC }}$. To trickle start, a 90 k resistor from the power line to $V_{\text {CC }}$ supplies the trickle current and C4 holds the $V_{\text {CC }}$ up while switching starts (see Figure 4). Then the auxiliary winding takes over and supplies the operating current. Note that D3 and the large value C3, in both Figures 4 and 5 , are only necessary for systems that have sudden large load variation down to minimum load and/or very light load conditions. Under these conditions, the loop may exhibit a start/restart mode because switching remains off Iong enough for C 4 to discharge below 10V. The C3 will hold $V_{C C}$ up until switching resumes. For less severe load variations, D3 is replaced with a short and C3 is omitted. The turns ratio between the primary winding and the

Figure 4. Power Supply for LT1249

Figure 5. Power Supply for LT1249
auxiliary winding determines $\mathrm{V}_{\text {CC }}$ according to: $\mathrm{V}_{\text {OUT }} /\left(\mathrm{V}_{\text {CC }}\right.$ $-2 \mathrm{~V})=\mathrm{N}_{\mathrm{p}} / \mathrm{N}_{\mathrm{S}}$. For 382V $\mathrm{V}_{\text {OUT }}$ and $18 \mathrm{~V} \mathrm{~V}_{\text {CC }}, N_{p} / N_{S} \approx 19$.
In Figure 5 a new technique for supply voltage eliminates the need for an extra inductor winding. It uses capacitor charge transfer to generate a constant current source which feeds a Zener diode. Current to the Zener is equal to $\left(V_{\text {OUT }}-V_{Z}\right)(C)(f)$, where $V_{Z}$ is Zener voltage and $f$ is switching frequency. For $\mathrm{V}_{\text {OUT }}=382 \mathrm{~V}, \mathrm{~V}_{\mathrm{Z}}=18 \mathrm{~V}, \mathrm{C}=$ 1000 pF and $\mathrm{f}=100 \mathrm{kHz}$, Zener current will be 36 mA . This is enough to operate the LT1249, including the FET gate drive.

## Output Capacitor

The peak-to-peak 120Hz output ripple is determined by:

$$
\begin{aligned}
& V_{P-P}=(2)\left(I_{\text {LOAD }} D C\right)(Z) \\
& \text { where } I_{\text {LOAD }} D C: D C \text { load current } \\
& \quad Z: \text { capacitor impedance at } 120 \mathrm{~Hz}
\end{aligned}
$$

For $180 \mu \mathrm{~F}$ at 300 W load, $\mathrm{l}_{\mathrm{LOAD}} \mathrm{DC}=300 \mathrm{~W} / 385 \mathrm{~V}=0.78 \mathrm{~A}$,

## APPLICATIONS INFORMATION

$V_{P-P}=(2)(0.78 \mathrm{~A})(7.4 \Omega)=11.5 \mathrm{~V}$. If less ripple is desired, higher capacitance should be used.
The selection of the output capacitor should also be based on the operating ripple current through the capacitor.
The ripple current can be divided into three major components. The first is at 120 Hz whose RMS value is related to the DC load current as follows:

$$
I_{\text {RMS }} \approx(0.71)\left(I_{\text {LOAD }} D C\right)
$$

The second component contains the PF switching frequency ripple current and its harmonics. Analysis of this ripple is complicated because it is modulated with a 120 Hz signal. However, computer numerical integration and Fourier analysis approximate the RMS value reasonably close to the bench measurements. The RMS value is about 0.82 A at a typical condition of 120VAC, 200W load. This ripple is line voltage dependent, and the worst case is at low line.

$$
I_{2 R M S}=0.82 \mathrm{~A} \text { at } 120 \mathrm{VAC}, 200 \mathrm{~W}
$$

The third component is the switching ripple from the load, if the load is a switching regulator.

$$
I_{3 R M S} \approx I_{\text {LOAD }} D C
$$

For United Chemicon KMH 400V capacitor series, ripple current multiplier for currents at 100 kHz is 1.43 . The equivalent 120 Hz ripple current can then be found:

$$
I_{\text {RMS }}=\sqrt{\left(I_{1 R M S}\right)^{2}+\left(\frac{I_{2 R M S}}{1.43}\right)^{2}+\left(\frac{I_{3 R M S}}{1.43}\right)^{2}}
$$

For a typical system that runs at an average load of 200W and 385 V output:

$$
\begin{aligned}
& I_{\text {LOAD }} D C=0.52 \mathrm{~A} \\
& I_{1 \text { RMS }} \approx(0.71)(0.52 \mathrm{~A})=0.37 \mathrm{~A} \\
& I_{2 R M S} \approx 0.82 \mathrm{~A} \text { at } 120 \mathrm{VAC} \\
& I_{3 \text { RMS }} \approx I_{\text {LOAD }} D C=0.52 \mathrm{~A}
\end{aligned}
$$

$$
\mathrm{I}_{\mathrm{RMS}}=\sqrt{(0.37 \mathrm{~A})^{2}+\left(\frac{0.82 \mathrm{~A}}{1.43}\right)^{2}+\left(\frac{0.52 \mathrm{~A}}{1.43}\right)^{2}}=0.77 \mathrm{~A}
$$

The 120 Hz ripple current rating at $105^{\circ} \mathrm{C}$ ambient is 0.95 A for the $180 \mu \mathrm{FKMH} 400 \mathrm{~V}$ capacitor. The expected life of the output capacitor may be calculated from the thermal stress analysis:

$$
\mathrm{L}=\left(\mathrm{L}_{0}\right)(2) \frac{\left(105^{\circ} \mathrm{C}+\Delta \mathrm{T}_{\mathrm{K}}\right)-\left(\mathrm{T}_{\mathrm{AMB}}+\Delta \mathrm{T}_{0}\right)}{10}
$$

where
$L=$ expected life time
$L_{0}=$ hours of load life at rated ripple current and rated ambient temperature
$\Delta T_{K}=$ capacitor internal temperature rise at rated condition. $\Delta T_{K}=\left(I^{2} R\right) /(K A)$, where $I$ is the rated current, $R$ is capacitor ESR, and KA is a volume constant.
$\mathrm{T}_{\text {AMB }}=$ operating ambient temperature
$\Delta T_{0}=$ capacitor internal temperature rise at operating condition
In our example, $\mathrm{L}_{0}=2000$ hours and $\Delta \mathrm{T}_{\mathrm{K}}=10^{\circ} \mathrm{C}$ at rated 0.95A. $\Delta \mathrm{T}_{0}$ can then be calculated from:

$$
\Delta \mathrm{T}_{0}=\left(\frac{\mathrm{I}_{\mathrm{RMS}}}{0.95 \mathrm{~A}}\right)^{2}\left(\Delta \mathrm{~T}_{\mathrm{K}}\right)=\left(\frac{0.77 \mathrm{~A}}{0.95 \mathrm{~A}}\right)^{2}\left(10^{\circ} \mathrm{C}\right)=6.6^{\circ} \mathrm{C}
$$

Assuming the operating ambient temperature is $60^{\circ} \mathrm{C}$, the approximate life time is:

$$
\begin{aligned}
\mathrm{L}_{0} & \approx(2000)(2) \frac{\left(105^{\circ} \mathrm{C}+10^{\circ} \mathrm{C}\right)-\left(60^{\circ} \mathrm{C}+6.6^{\circ} \mathrm{C}\right)}{10} \\
& \approx 57,000 \mathrm{Hrs} .
\end{aligned}
$$

For longer life, capacitor with higher ripple current rating or parallel capacitors should be used.

## Protection Against Abnormal Current Surge Conditions

The LT1249 has an upper limit on the allowed voltage across the current sense resistor. The voltage into the $\mathrm{M}_{\text {OUt }}$ pin connected to this resistor must not exceed -6V while the chip is running and -12 V under any conditions. The LT1249 gate drive will malfunction if the $\mathrm{M}_{\text {OUt }}$ pin voltage exceeds -6 V while $\mathrm{V}_{\text {CC }}$ is powered, destroying the power FET. The 12 V absolute limit is imposed by ESD clamps on the $\mathrm{M}_{\text {OUt }}$ pin. Large currents will flow at

## APPLICATIONS InFORMATION

voltages above 8 V and the 12 V limit is only for surge conditions.

In normal operation, the voltage into $\mathrm{M}_{\text {Out }}$ does not exceed 1.1V, but under surge conditions, the voltage could temporarily go higher. To date, no field failures due to surges have been reported for normal LT1249 configurations, but if the possibility exists for extremely large current surges, please read the following discussion.

Offline switching power supplies can create large current surges because of the high value storage capacitor used. The surge can be the result of closing the line switch near the peak of the AC line voltage, or because of a large transient in the line itself. These surges are well known in the power supply business, and are normally controlled with a negative temperature coefficient thermistor in series with the rectifier bridge. When power is switched on, the thermistor is cold (high resistance) and surges are limited. Current flow in the thermistor causes it to heat and resistance drops to the point where overall efficiency loss in the resistor is acceptable.

This basic protection mechanism can be partially defeated if the power supply is switched off for a few seconds, then turned back on. The thermistor has not had time to cool significantly and if the subsequent turn-on catches the AC line near its peak, the resulting surge is much higher than normal. Even if this surge current generates a voltage greater than 6 V (but less than 12 V ) across the sense
resistor, the standard LT1249 application will not be affected because the chip is not yet powered. Problems are only created if the $V_{\text {CC }}$ pin is powered from some external housekeeping supply that remains powered when bridge power is switched off.

A huge line voltage surge, beyond the normal worst-case limits, can also create a large current surge. The peak of the line voltage must significantly exceed the storage capacitor voltage (typically 380V) for this to occur, so peak line voltage would probably have to exceed 450 V . Such excessive surges might occur if a very large mains load was suddenly removed, with a resulting line "kickback". If the surge results in voltage at the $\mathrm{M}_{\text {OUT }}$ pin greater than 6 V , it must also last more than $30 \mu \mathrm{~s}$ (three switch cycles) to cause FET problems.

## External Clamp

The external clamp shown in Figure 6 will protect the LT1249 M M surges (see above). Protection is provided for all $V_{C C}$ power methods. The $100 \Omega$ resistor and three diodes limit the peak negative voltage into $\mathrm{M}_{\text {Out }}$ to less than 3 V . Current sense gain is attenuated by only $100 \Omega / 4000 \Omega=$ $2.5 \%$. Three diodes are used because the peak negative voltage into $\mathrm{M}_{\text {Out }}$ in normal operation could go as high as -1.1 V and the diodes should not conduct more than a few microamps under this condition.

## TYPICAL APPLICATION

## RELATGD PARTS

| PART NUMBER | DESCRIPTION | COMMENTS |
| :--- | :--- | :--- |
| LT1103 | Off-Line Switching Regulator | Universal Off-Line Inputs with Outputs to 100W |
| LT1248 | Full Feature Average Current Mode Power Factor Controller | Provides All Features in 16-Lead Package |
| LT1508 | Power Factor and PWM Controller | Simplified PFC Design |
| LT1509 | Power Factor and PWM Controller | Complete Solution for Universal Off-Line Switching Power Supplies |
