

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

BLOCK DIAGRAM

PIN FUNCTIONS

SHDN (Pin 1): Shutdown Input. A logic low on the SHDN pin puts the part into shutdown mode. A logic high ($V_{SHDN} \geq 1.6V$) enables the charge pump regulator. At high V_{IN} voltages, the SHDN pin may still be controlled with 3V logic without causing a large rise in V_{IN} quiescent current. The SHDN pin may not float; connect to V_{IN} if unused.

LBO (Pin 2): Open-Drain, Low-Battery Comparator Output. This pin will pull low whenever the voltage on the LBI pin is less than the internal reference voltage (1.145V typ).

LBI (Pin 3): Low-Battery Comparator Input. The voltage on this pin is compared to the internal reference voltage (1.145V). The LBO output will sink current when the voltage on the LBI pin is less than 1.145V typ. The low-

PIN FUNCTIONS

battery comparator and 1.145V reference are kept alive in shutdown.

GND (Pin 4): Ground. Should be tied to a ground plane for best performance.

C1⁻ (Pin 5): Charge Pump Flying Capacitor, Negative Terminal.

C1⁺ (Pin 6): Charge Pump Flying Capacitor, Positive Terminal.

V_{IN} (Pin 7): Charge Pump Input Voltage. May be between 2V and 8V (LTC1514-3.3) or between 2.7V and 10V (LTC1514-5). V_{IN} should be bypassed with a $\geq 10\mu\text{F}$ low ESR capacitor as close as possible to the pin for best performance.

V_{OUT} (Pin 8): Regulated Output Voltage. The output voltage is internally set to either 3.3V (LTC1514-3.3) or to 5V (LTC1514-5) using an internal resistor divider. V_{OUT} should be bypassed with a $\geq 10\mu\text{F}$ low ESR capacitor as close as possible to the pin for best performance.

APPLICATIONS INFORMATION

Regulator Operation

The regulator section of the LTC1514-3.3/LTC1514-5 consists of a charge pump, reference, comparator and some logic. The divided down output voltage is compared to the internal reference voltage. When the divided output drops below the reference voltage, the charge pump is enabled, which boosts the output back into regulation. Hysteresis in the comparator forces the regulator to burst on and off and causes approximately 100mV of peak-to-peak ripple to appear at the output. By enabling the charge pump only when needed, the LTC1514-3.3 and LTC1514-5 are able to achieve high efficiencies with low output load currents.

Each part's charge pump has a unique architecture that allows the input voltage to be either stepped up or stepped down to produce a regulated output. Internal circuitry senses the V_{IN} to V_{OUT} differential voltage and controls the charge pump operating mode. In addition, the effective output impedance of the charge pump is internally adjusted to prevent large inrush currents and allow for a wide input voltage range. When the input voltage is lower than the output voltage, the charge pump operates as a step-up voltage doubler. When the input voltage is greater than the output, the charge pump operates as a step-down gated switch.

Capacitor Selection

For best performance, low ESR capacitors are recommended for both C_{IN} and C_{OUT} to reduce noise and ripple. The C_{IN} and C_{OUT} capacitors should be either ceramic or

tantalum and should be 10 μF or greater. If the input source impedance is very low ($< 0.5\Omega$), C_{IN} may not be needed. Increasing the size of C_{OUT} to 22 μF or greater will reduce output voltage ripple—particularly with high V_{IN} voltages (8V or greater). A ceramic capacitor is recommended for the flying capacitor C1 with a value of 0.1 μF or 0.22 μF . Smaller value flying capacitors may be used in low output current applications.

Output Ripple

Normal LTC1514-3.3/LTC1514-5 operation produces voltage ripple on the V_{OUT} pin. Output voltage ripple is required for the parts to regulate. Low frequency ripple exists due to the hysteresis in the sense comparator and propagation delays in the charge pump enable/disable circuits. High frequency ripple is also present mainly from the ESR (equivalent series resistance) in the output capacitor. Typical output ripple (V_{IN} < 8V) under maximum load is 100mV peak-to-peak with a low ESR ($< 0.5\Omega$) 10 μF output capacitor. For applications requiring V_{IN} to exceed 8V, a 22 μF or larger C_{OUT} capacitor is recommended to maintain max ripple in the 100mV range.

The magnitude of the ripple voltage depends on several factors. High input voltages increase the output ripple since more charge is delivered to C_{OUT} per charging cycle. A large C1 flying capacitor ($> 0.22\mu\text{F}$) also increases ripple in step-up mode for the same reason. Large output current load and/or a small output capacitor ($< 10\mu\text{F}$) results in higher ripple due to higher output voltage dV/dt. High ESR capacitors (ESR $> 0.5\Omega$) on the

APPLICATIONS INFORMATION

output pin cause high frequency voltage spikes on V_{OUT} with every clock cycle.

There are several ways to reduce the output voltage ripple. A larger C_{OUT} capacitor (22 μ F or greater) will reduce both the low and high frequency ripple due to the lower C_{OUT} charging and discharging dV/dt and the lower ESR typically found with higher value (larger case size) capacitors. A low ESR ceramic output capacitor will minimize the high frequency ripple, but will not reduce the low frequency ripple unless a high capacitance value is chosen. A reasonable compromise is to use a 10 μ F to 22 μ F tantalum capacitor in parallel with a 1 μ F to 3.3 μ F ceramic capacitor on V_{OUT} to reduce both the low and high frequency ripple. An RC or LC filter may also be used to reduce high frequency voltage spikes (see Figure 1).

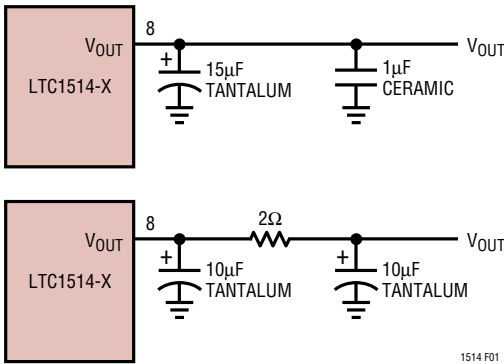

Figure 1. Output Ripple Reduction Techniques

Inrush Currents

A common problem with switched capacitor regulators is inrush current—particularly during power-up and coming out of shutdown mode. Whenever large V_{IN} (or boosted V_{IN}) to V_{OUT} voltage differentials are present, most charge pumps will pull large current spikes from the input supply. Only the effective charge pump output impedance limits the current while the charge pump is enabled. This may disrupt input supply regulation, especially if the input supply is a low power DC/DC converter or linear regulator. The LTC1514-3.3/LTC1514-5 minimize inrush currents both at start-up and under normal high V_{IN} to V_{OUT} operation.

Internal soft start circuitry controls the rate at which V_{OUT} may be charged from 0V to its final regulated value. The typical start-up time from $V_{OUT} = 0V$ to 5V is 4ms. This corresponds to an effective V_{OUT} charging current of only 12.5mA for a 10 μ F output capacitor (27.5mA for 22 μ F, etc). Note that any output current load present during start-up will add directly to the charging currents mentioned above. The soft start circuitry limits start-up current both at initial power-up and when coming out of shutdown.

As the V_{IN} (or boosted V_{IN}) to V_{OUT} voltage differential grows, the effective output impedance of the charge pump is automatically increased by internal voltage sensing circuitry. This feature minimizes the current spikes pulled from V_{IN} whenever the charge pump is enabled and helps to reduce both input and output ripple.

Protection Features

The LTC1514-X contain thermal shutdown and short-circuit protection features. The parts will shut down when the junction temperature reaches approximately 150°C and will resume operation once the junction temperature has dropped back to approximately 140°C. The parts will limit output current to 12mA (typ) when a short-circuit condition ($V_{OUT} < 100mV$) exists. The parts can survive an indefinite short to GND. The LTC1514-X devices use a low thermal resistance SO-8 package (110°C/W vs 150°C/W for standard SO-8). This permits full output current, even at high input supply voltages.

Low-Battery Comparator

The internal low-battery comparator trips at $1.145 \pm 3\%$ (LBI ramping negative). Programming the comparator to trip at a higher voltage can easily be done with an external

Figure 2. Programming the Low-Battery Comparator Trip Voltage

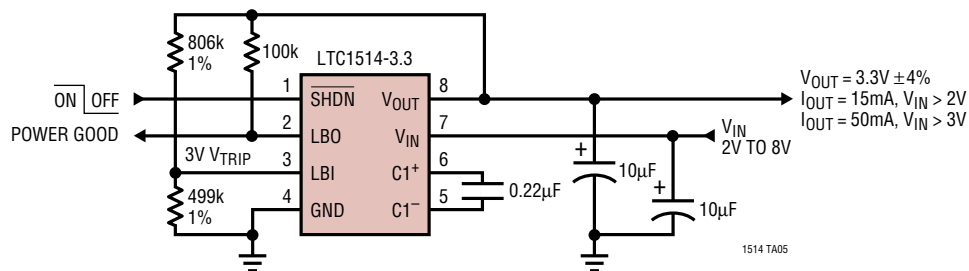

APPLICATIONS INFORMATION

resistor divider (see Figure 2). Since the low-battery comparator is kept alive in shutdown, it may be used to protect batteries against deep discharge by shutting down the power supply when the battery voltage gets too

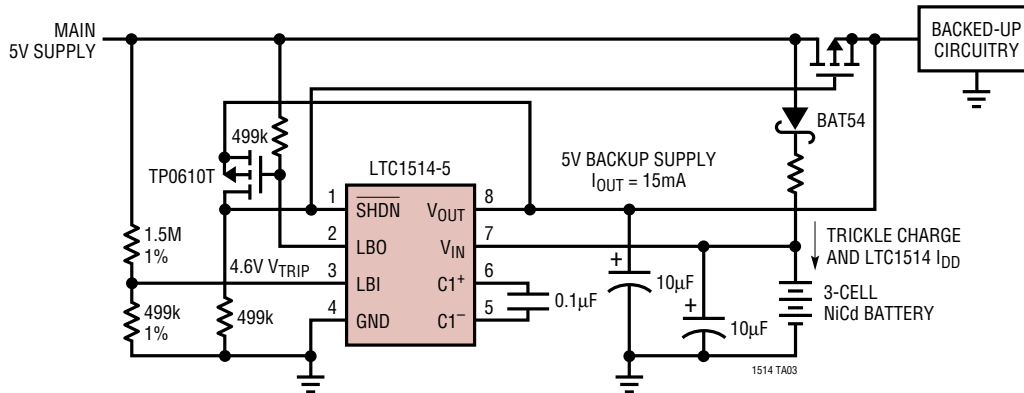

low. The open-drain comparator output allows for flexible interfacing between the LBO output and external logic. LBO pull-up resistors in the 50k to 1M range are recommended.
