

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# 16-Bit, 200ksps, Serial ADC with Multiple Input Ranges

## FEATURES

- **Sample Rate: 200ksps**
- **Input Ranges**  
**Unipolar: 0V to 10V, 0V to 5V and 0V to 4V**  
**Bipolar: ±10V, ±5V and ±3.3V**
- **Guaranteed No Missing Codes**
- Serial I/O
- Single 5V Supply
- Power Dissipation: 65mW Typ
- Power Down Mode: 50μW
- SNR: 87dB Typ
- Operates with Internal or External Reference
- 28-Pin SSOP and 20-Pin SO Packages
- Improved 2nd Source to ADS7809 and AD977A

## APPLICATIONS

- Industrial Process Control
- Multiplexed Data Acquisition Systems
- High Speed Data Acquisition for PCs
- Digital Signal Processing

## DESCRIPTION

The LTC<sup>®</sup>1609 is a 200ksps, serial sampling 16-bit A/D converter that draws only 65mW (typical) from a single 5V supply. This easy-to-use device includes a sample-and-hold, a precision reference, a switched capacitor successive approximation A/D and trimmed internal clock.

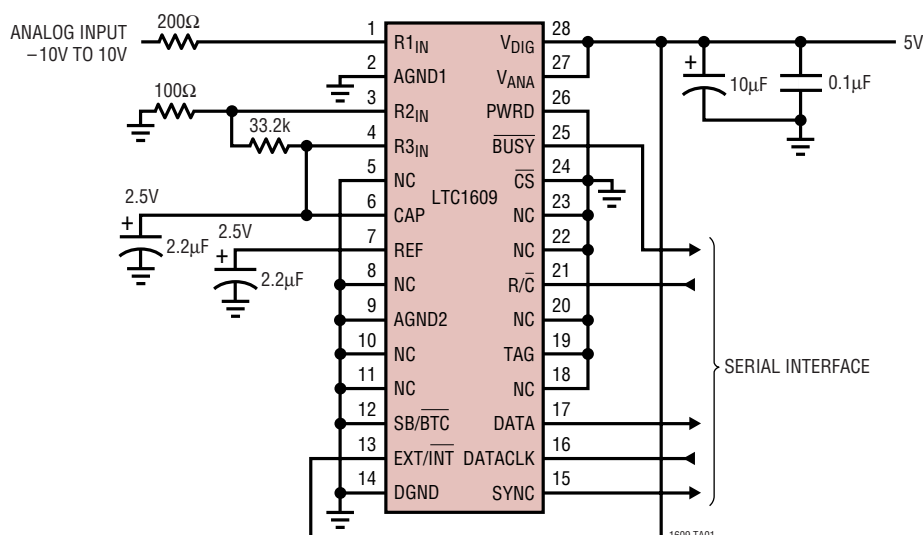

The input range is specified for bipolar inputs of ±10V, ±5V and ±3.3V and unipolar inputs of 0V to 10V, 0V to 5V and 0V to 4V. Maximum DC specs include ±2LSB INL and 16-bit no missing codes over temperature. It has a typical signal-to-noise ratio of 87dB.

The ADC has a high speed serial interface. The serial output data can be clocked out using either the internal serial shift clock or be clocked out by an external shift clock. A separate convert start input ( $R/\bar{C}$ ) and a data ready signal ( $BUSY$ ) ease connections to FIFOs, DSPs and microprocessors.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.

## TYPICAL APPLICATION

200kHz, 16-Bit Serial Sampling ADC Configured for ±10V Inputs

1609 TA01

## POWER REQUIREMENTS

The ● indicates specifications which apply over the full operating temperature range, otherwise specifications are at  $T_A = 25^\circ\text{C}$ . (Note 5)

SYMBOL	PARAMETER	CONDITIONS	LTC1609/LTC1609A			UNITS
			MIN	TYP	MAX	
$V_{DD}$	Positive Supply Voltage	(Notes 9, 10)	4.75		5.25	V
$I_{DD}$	Positive Supply Current	PWRD = Low ●		13	20	mA
$P_{DIS}$	Power Dissipation	PWRD = Low PWRD = High		65 50	100	mW $\mu\text{W}$

**Note 1:** Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

**Note 2:** All voltage values are with respect to ground with DGND, AGND1 and AGND2 wired together (unless otherwise noted).

**Note 3:** When these pin voltages are taken below ground or above  $V_{ANA} = V_{DIG} = V_{DD}$ , they will be clamped by internal diodes. This product can handle input currents of greater than 100mA below ground or above  $V_{DD}$  without latch-up.

**Note 4:** When these pin voltages are taken below ground, they will be clamped by internal diodes. This product can handle input currents of 90mA below ground without latchup. These pins are not clamped to  $V_{DD}$ .

**Note 5:**  $V_{DD} = 5\text{V}$ ,  $f_{SAMPLE} = 200\text{kHz}$ ,  $t_r = t_f = 5\text{ns}$  unless otherwise specified.

**Note 6:** Linearity, offset and full-scale specifications apply for a  $V_{IN}$  input with respect to ground.

**Note 7:** Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual end points of the transfer curve. The deviation is measured from the center of the quantization band.

**Note 8:** Bipolar zero error is the offset voltage measured from  $-0.5\text{LSB}$  when the output code flickers between 0000 0000 0000 0000 and 1111 1111 1111 1111. Unipolar zero error is the offset voltage measured from  $0.5\text{LSB}$  when the output codes flickers between 0000. . .0000 and 0000. . .0001.

**Note 9:** Guaranteed by design, not subject to test.

**Note 10:** Recommended operating conditions.

**Note 11:** With  $\overline{CS}$  low the falling  $R/\overline{C}$  edge starts a conversion. If  $R/\overline{C}$  returns high at a critical point during the conversion it can create small errors. For best results ensure that  $R/\overline{C}$  returns high within  $1.2\mu\text{s}$  after the start of the conversion.

**Note 12:** As measured with fixed 1% resistors shown in Figures 3a and 3b. Adjustable to zero with external potentiometer.

**Note 13:** Full-scale error is the worst-case of  $-FS$  or  $+FS$  untrimmed deviation from ideal first and last code transitions, divided by the transition voltage (not divided by the full-scale range) and includes the effect of offset error. For unipolar input ranges full-scale error is the deviation of the last code transition from ideal divided by the transition voltage and includes the effect of offset error.

**Note 14:** All specifications in dB are referred to a full-scale  $\pm 5\text{V}$  input.

**Note 15:** Full-power bandwidth is defined as full-scale input frequency at which a signal-to-(noise + distortion) degrades to 60dB or 10 bits of accuracy.

**Note 16:** Recovers to specified performance after  $(2 \bullet FS)$  input overvoltage.

**Note 17:** When data is shifted out during a conversion, with an external data clock, complete the process within  $1.2\mu\text{s}$  from the start of the conversion ( $\overline{BUSY}$  falling). This will help keep any external disturbances from causing an error in the conversion result.

## PIN FUNCTIONS (20-Pin SO/28-Pin SSOP)

**R1<sub>IN</sub> (Pin 1/Pin 1):** Analog Input. See Table 1 and Figure 1 for input range connections.

**AGND1 (Pin 2/Pin 2):** Analog Ground. Tie to analog ground plane.

**R2<sub>IN</sub> (Pin 3/Pin 3):** Analog Input. See Table 1 and Figure 1 for input range connections.

**R3<sub>IN</sub> (Pin 4/Pin 4):** Analog Input. See Table 1 and Figure 1 for input range connections.

**NC (28-Pin SSOP Only—Pins 5, 8, 10, 11, 18, 20, 22, 23):** No Connect.

**CAP (Pin 5/Pin 6):** Reference Buffer Output. Bypass with 2.2μF tantalum capacitor.

**REF (Pin 6/Pin 7):** 2.5V Reference Output. Bypass with 2.2μF tantalum capacitor. Can be driven with an external reference.

**AGND2 (Pin 7/Pin 9):** Analog Ground. Tie to analog ground plane.

**SB/ $\overline{\text{BTC}}$  (Pin 8/Pin 12):** Select straight binary or two's complement data output format. Tie pin high for straight binary or tie low for two's complement format.

**EXT/ $\overline{\text{INT}}$  (Pin 9/Pin 13):** Select external or internal clock for shifting out the output data. Tie the pin high to synchronize the output data to the clock that is applied to the DATACLK pin. If the pin is tied low, a convert command will start transmitting the output data from the previous conversion synchronized to 16 clock pulses that are outputted on the DATACLK pin.

**DGND (Pin 10/Pin 14):** Digital Ground.

**SYNC (Pin 11/Pin 15):** Sync Output. If EXT/ $\overline{\text{INT}}$  is high, either a rising edge on R/ $\overline{\text{C}}$  with  $\overline{\text{CS}}$  low or a falling edge on  $\overline{\text{CS}}$  with R/ $\overline{\text{C}}$  high will output a pulse on SYNC synchronized to the external clock applied on the DATACLK pin.

**DATACLK (Pin 12/Pin 16):** Either an input or an output depending on the level set on EXT/ $\overline{\text{INT}}$ . The output data is synchronized to this clock. When EXT/ $\overline{\text{INT}}$  is high an external shift clock is applied to this pin. If EXT/ $\overline{\text{INT}}$  is taken

low, 16 clock pulses are output during each conversion. The pin will stay low between conversions.

**DATA (Pin 13/Pin 17):** Serial Data Output. The output data is synchronized to the DATACLK and the format is determined by SB/ $\overline{\text{BTC}}$ . In the external shift clock mode, after 16 bits of data have been shifted out and  $\overline{\text{CS}}$  is low and R/ $\overline{\text{C}}$  is high, the level in the TAG pin will be outputted. This can be used to daisy-chain the serial data output from several LTC1609s. If EXT/ $\overline{\text{INT}}$  is low, the output data is valid on both the rising and falling edge of the internal shift clock which is outputted on DATACLK. In between conversions, DATA will stay at the level of the TAG input when the conversion was started.

**TAG (Pin 14/Pin 19):** Tag input is used in the external clock mode. If EXT/ $\overline{\text{INT}}$  is high, digital inputs applied to TAG will be shifted out on DATA delayed 16 DATACLK pulses as long as  $\overline{\text{CS}}$  is low and R/ $\overline{\text{C}}$  is high.

**R/ $\overline{\text{C}}$  (Pin 15/Pin 21):** Read/ $\overline{\text{Convert}}$  Input. With  $\overline{\text{CS}}$  low, a falling edge on R/ $\overline{\text{C}}$  puts the internal sample-and-hold into the hold state and starts a conversion. With  $\overline{\text{CS}}$  low, a rising edge on R/ $\overline{\text{C}}$  enables the serial output data.

**$\overline{\text{CS}}$  (Pin 16/Pin 24):**  $\overline{\text{Chip Select}}$ . Internally OR'd with R/ $\overline{\text{C}}$ . With R/ $\overline{\text{C}}$  low, a falling edge on  $\overline{\text{CS}}$  will initiate a conversion. With R/ $\overline{\text{C}}$  high, a falling edge on  $\overline{\text{CS}}$  will enable the serial output data.

**$\overline{\text{BUSY}}$  (Pin 17/Pin 25):** Output Shows Converter Status. It is low when a conversion is in progress. Data valid on the rising edge of  $\overline{\text{BUSY}}$ .  $\overline{\text{CS}}$  or R/ $\overline{\text{C}}$  must be high when  $\overline{\text{BUSY}}$  rises or another conversion will start without time for signal acquisition.

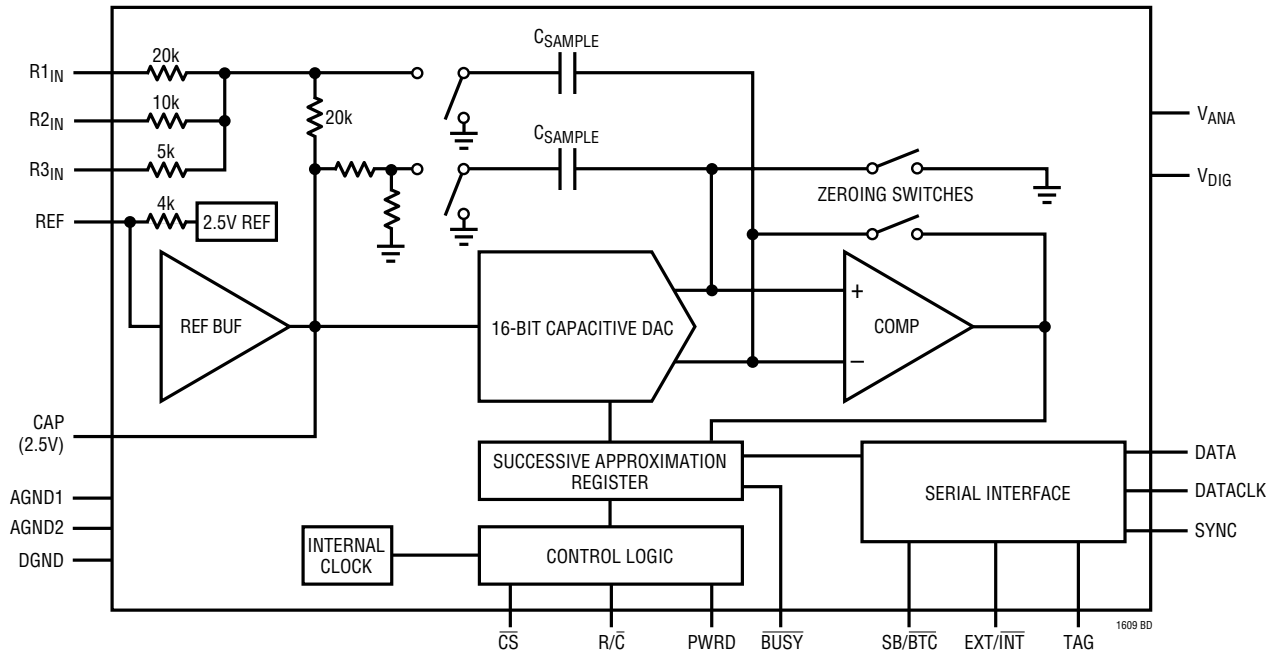

**PWRD (Pin 18/Pin 26):** Power Down Input. If the pin is tied high, conversions are inhibited and power consumption is reduced (10μA typ). Results from the previous conversion are maintained in the output shift register.

**V<sub>ANA</sub> (Pin 19/Pin 27):** 5V Analog Supply. Bypass to ground with a 0.1μF ceramic and a 10μF tantalum capacitor.

**V<sub>DIG</sub> (Pin 20/Pin 28):** 5V Digital Supply. Connect directly to V<sub>ANA</sub>.

## FUNCTIONAL BLOCK DIAGRAM

## APPLICATIONS INFORMATION

## Conversion Details

The LTC1609 uses a successive approximation algorithm and an internal sample-and-hold circuit to convert an analog signal to a 16-bit serial output. The ADC is complete with a precision reference and an internal clock. The control logic provides easy interface to microprocessors and DSPs. (Please refer to the Digital Interface section for timing information.)

Conversion start is controlled by the  $\overline{CS}$  and  $R/\overline{C}$  inputs. At the start of conversion the successive approximation register (SAR) is reset. Once a conversion cycle has begun it cannot be restarted.

During the conversion, the internal 16-bit capacitive DAC output is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB). Referring to Figure 1,  $V_{IN}$  is connected through the resistor divider to the sample-and-hold capacitor during the acquire phase and the comparator offset is nulled by the autozero switches. In this acquire phase, a minimum delay of  $2\mu\text{s}$  will provide enough time for the sample-and-hold capacitor to acquire

the analog signal. During the convert phase, the autozero switches open, putting the comparator into the compare mode. The input switch switches  $C_{SAMPLE}$  to ground, injecting the analog input charge onto the summing junction. This input charge is successively compared with the binary-weighted charges supplied by the capacitive DAC. Bit decisions are made by the high speed comparator. At

Figure 1. LTC1609 Simplified Equivalent Circuit

1609fa

## APPLICATIONS INFORMATION

the end of a conversion, the DAC output balances the  $V_{IN}$  input charge. The SAR contents (a 16-bit data word) that represents the  $V_{IN}$  are loaded into the 16-bit output shift register.

### Driving the Analog Inputs

The LTC1609 analog input ranges, along with the nominal input impedances, are shown in Tables 1a and 1b. The inputs are overvoltage protected to  $\pm 25V$ . The input impedance can get as low as  $10k\Omega$ , therefore, it should be driven with a low impedance source. Wideband noise coupling into the input can be minimized by placing a  $1000pF$  capacitor at the input as shown in Figure 2. An NPO-type capacitor gives the lowest distortion. Place the capacitor as close to the device input pin as possible. If an amplifier is to be used to drive the input, care should be taken to select an amplifier with adequate accuracy, linearity and noise for the application. The following list is a summary of the op amps that are suitable for driving the LTC1609. More detailed information is available in the Linear Technology data books and LinearView™ CD-ROM.

Figure 2. Analog Input Filtering

LT1007 - Low noise precision amplifier. 2.7mA supply current  $\pm 5V$  to  $\pm 15V$  supplies. Gain bandwidth product 8MHz. DC applications.

LT1097 - Low cost, low power precision amplifier.  $300\mu A$  supply current.  $\pm 5V$  to  $\pm 15V$  supplies. Gain bandwidth product 0.7MHz. DC applications.

LT1227 - 140MHz video current feedback amplifier. 10mA supply current.  $\pm 5V$  to  $\pm 15V$  supplies. Low noise and low distortion.

LT1360 - 37MHz voltage feedback amplifier. 3.8mA supply current.  $\pm 5V$  to  $\pm 15V$  supplies. Good AC/DC specs.

LT1363 - 50MHz voltage feedback amplifier. 6.3mA supply current. Good AC/DC specs.

LT1364/LT1365 - Dual and quad 50MHz voltage feedback amplifiers. 6.3mA supply current per amplifier. Good AC/DC specs.

LT1468 - 90MHz,  $22V/\mu s$  16-bit accurate amplifier

LT1469 - Dual LT1468

### Offset and Gain Adjustments

The LTC1609 is specified to operate with three unipolar and three bipolar input ranges. Pins  $R1_{IN}$ ,  $R2_{IN}$  and  $R3_{IN}$  are connected as shown in Tables 1a and 1b for the different input ranges. The tables also list the nominal input impedance for each range. Table 1c shows the output codes for the ideal input voltages of each of the six input ranges.

The LTC1609 offset and full-scale errors have been trimmed at the factory with the external resistors shown in Figures 3a and 3b. This allows for external adjustment of offset and full scale in applications where absolute accuracy is important. The offset and gain adjustment circuits for the six input ranges are also shown in Figures 3a and 3b. To adjust the offset for a bipolar input range, apply an input voltage equal to  $-0.5LSB$  where  $1LSB = (+FS - -FS)/65536$  and change the offset resistor so the output code is changing between 1111 1111 1111 1111 and 0000 0000 0000 0000. The gain is trimmed by applying an input voltage of  $+FS - 1.5LSB$  and adjusting the gain trim resistor until the output code is changing between 0111 1111 1111 1110 and 0111 1111 1111 1111. In both cases the data is in two's complement format ( $SB/\overline{BTC} = LOW$ )

To adjust the offset for a unipolar input range, apply an input voltage equal to  $+0.5LSB$  where  $1LSB = +FS/65536$ . Then adjust the offset trim resistor until the output code changes between 0000 0000 0000 0000 and 0000 0000 0000 0001. To adjust the gain, apply an input voltage equal to  $+FS - 1.5LSB$  and vary the gain trimming resistor until the output code is changing between 1111 1111 1111 1110 and 1111 1111 1111 1111. In the unipolar case, the data is in straight binary format ( $SB/\overline{BTC} = HIGH$ ). Figures 4a and 4b show the transfer characteristics of the LTC1609.

Figure 4a. LTC1609 Bipolar Transfer Characteristics

Figure 4b. LTC1609 Unipolar Transfer Characteristics

The ideal  $\pm FS$  value for the  $\pm 3.3V$  range is  $3.340000V - 1LSB$  and  $-3.340000V$ , respectively. The external  $33.2k$  resistor that is connected between the CAP pin and the  $R2_{IN}$  pin, slightly attenuates the input signal applied to  $R2_{IN}$ . Without the  $33.2k$  resistor the  $\pm FS$  value would be  $3.333333V - 1LSB$  and  $-3.333333V$  (zero volt offset), respectively.

### DC Performance

One way of measuring the transition noise associated with a high resolution ADC is to use a technique where a DC signal is applied to the input of the ADC and the resulting output codes are collected over a large number of conversions. For example in Figure 5 the distribution of output code is shown for a DC input that has been digitized 4096 times. The distribution is Gaussian and the RMS code transition is about  $0.9LSB$ .

Figure 5. Histogram for 4096 Conversions

## APPLICATIONS INFORMATION

### Dynamic Performance

FFT (Fast Fourier Transform) test techniques are used to test the ADC's frequency response, distortion and noise at the rated throughput. By applying a low distortion sine wave and analyzing the digital output using an FFT algorithm, the ADC's spectral content can be examined for frequencies outside the fundamental. Figure 6 shows a typical LTC1609 FFT plot which yields a SINAD of 87.2dB and THD of  $-100$ dB.

### Signal-to-Noise Ratio

The Signal-to-Noise and Distortion Ratio (SINAD) is the ratio between the RMS amplitude of the fundamental input frequency to the RMS amplitude of all other frequency components at the A/D output. The output is band limited to frequencies from above DC and below half the sampling frequency. Figure 6 shows a typical SINAD of 87.2dB with a 200kHz sampling rate and a 1kHz input.

Figure 6. LTC1609 Nonaveraged 4096 Point FFT Plot

### Total Harmonic Distortion

Total Harmonic Distortion (THD) is the ratio of the RMS sum of all harmonics of the input signal to the fundamental itself. The out-of-band harmonics alias into the frequency band between DC and half the sampling frequency. THD is expressed as:

$$\text{THD} = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 \dots + V_N^2}}{V_1}$$

where  $V_1$  is the RMS amplitude of the fundamental frequency and  $V_2$  through  $V_N$  are the amplitudes of the second through Nth harmonics.

### Internal Voltage Reference

The LTC1609 has an on-chip, temperature compensated, curvature corrected, bandgap reference, which is factory trimmed to 2.50V. The full-scale range of the ADC scales with  $V_{REF}$ . The output of the reference is connected to the input of a unity-gain buffer through a 4k resistor (see Figure 7). The input to the buffer or the output of the reference is available at REF. The internal reference can be overdriven with an external reference if more accuracy is needed. The buffer output drives the internal DAC and is available at CAP. The CAP pin can be used to drive a steady DC load of less than 2mA. Driving an AC load is not recommended because it can cause the performance of the converter to degrade.

For minimum code transition noise the REF pin and the CAP pin should each be decoupled with a capacitor to filter wideband noise from the reference and the buffer (2.2 $\mu$ F tantalum).

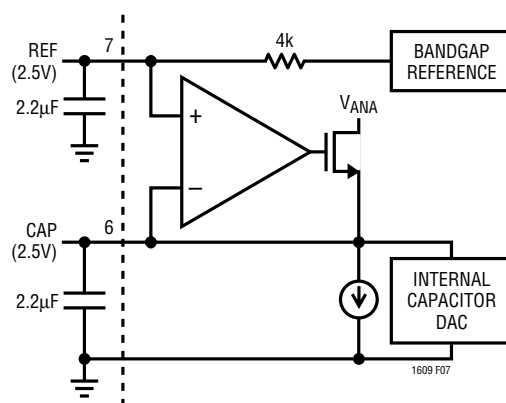

Figure 7. Internal or External Reference Source

## APPLICATIONS INFORMATION

### Power Shutdown

When the PWRD pin is tied high, power consumption drops to a typical value of  $50\mu\text{W}$  from a specified maximum of  $100\text{mW}$ . In the power shutdown mode, the result from the previous conversion is still available in the internal shift register, assuming the data had not been clocked out before going into power shutdown.

The internal reference buffer and the reference are shut down, so the power-up recovery time will be dependent upon how fast the bypass capacitors on these pins can be charged. If the internal reference is used, the  $4\text{k}\Omega$  resistor in series with the output and the external bypass capacitor, typically  $2.2\mu\text{F}$ , will be the main time constant for the power-up recovery time. If an external reference is used, the reference buffer output will be able to ramp from  $0\text{V}$  to  $2.5\text{V}$  in  $1\text{ms}$ , while charging a typical bypass capacitor of  $2.2\mu\text{F}$ . The recovery time will be less if the bypass capacitor has not completely discharged.

### DIGITAL INTERFACE

#### Internal Conversion Clock

The ADC has an internal clock that is trimmed to achieve a typical conversion time of  $2.7\mu\text{s}$ . No external adjustments are required and, with the typical acquisition time of  $1.5\mu\text{s}$ , throughput performance of  $200\text{ksps}$  is assured.

#### Timing and Control

Conversion start and data read are controlled by two digital inputs:  $\overline{\text{CS}}$  and  $\text{R}/\overline{\text{C}}$ . To start a conversion and put

the sample-and-hold into the hold mode bring  $\overline{\text{CS}}$  and  $\text{R}/\overline{\text{C}}$  low for no less than  $40\text{ns}$ . Once initiated it cannot be restarted until the conversion is complete. Converter status is indicated by the  $\overline{\text{BUSY}}$  output and this is low while the conversion is in progress.

The conversion result is clocked out serially on the DATA pin. It can be synchronized by using the internal data clock or by using an external clock provided by the user. Tying the  $\overline{\text{EXT}}/\overline{\text{INT}}$  pin high puts the LTC1609 in the external clock mode and the DATACLK pin is a digital input. Tying the  $\overline{\text{EXT}}/\overline{\text{INT}}$  pin low puts the part in the internal clock mode and the DATACLK pin becomes a digital output.

#### Internal Clock Mode

With the  $\overline{\text{EXT}}/\overline{\text{INT}}$  pin tied low, the LTC1609 provides the data clock on the DATACLK pin. The timing diagram is shown in Figure 8. Typically,  $\overline{\text{CS}}$  is tied low and the  $\text{R}/\overline{\text{C}}$  pin is used to start a conversion. During the conversion a 16-bit word will be shifted out MSB-first on the DATA pin. This word represents the result from the previous conversion. The DATACLK pin outputs 16 clock pulses used to synchronize the data. The output data is valid on both the rising and falling edges of the clock. After the LSB bit has been clocked out, the DATA pin will take on the state of the TAG pin at the start of the conversion. The DATACLK pin goes low until the next conversion is requested. The data clock is derived from the internal conversion clock. To avoid errors from occurring during the current conversion, minimize the loading on the DATACLK pin and the DATA pin. For the best conversion results the external clock mode is recommended.

Figure 8. Serial Data Timing Using Internal Clock ( $\overline{\text{CS}}$ ,  $\overline{\text{EXT}}/\overline{\text{INT}}$  and TAG Tied Low)

1609fa

## APPLICATIONS INFORMATION

### External Clock Mode

With the  $\overline{\text{EXT/INT}}$  pin tied high, the  $\text{DATACLK}$  pin becomes a digital input and the LTC1609 can accept an externally supplied data clock. There are several ways in which the conversion results can be clocked out. The data can be clocked out during or after a conversion with a continuous or discontinuous data clock. Figures 9 to 12 show the timing diagram for each of these methods.

### External Discontinuous Data Clock Data Read After the Conversion

Figure 9 shows how the result from the current conversion can be read out after the conversion has been completed. The externally supplied data clock is running discontinuously.  $\text{R}/\overline{\text{C}}$  is used to initiate a conversion with  $\overline{\text{CS}}$  tied low. The conversion starts on the falling edge of  $\text{R}/\overline{\text{C}}$ .  $\text{R}/\overline{\text{C}}$  should be returned high within  $1.2\mu\text{s}$  to prevent the transition from disturbing the conversion. After the conversion has been completed ( $\overline{\text{BUSY}}$  returning high), a

pulse on the  $\text{SYNC}$  pin will be generated on the rising edge of  $\text{DATACLK} \#0$ . The  $\text{SYNC}$  output can be captured on the falling edge of  $\text{DATACLK} \#0$  or on the rising edge of  $\text{DATACLK} \#1$ . After the rising edge of  $\text{DATACLK} \#1$ , the  $\text{SYNC}$  output will go low and the MSB will be clocked out on the  $\text{DATA}$  pin. This bit can be latched on the falling edge of  $\text{DATACLK} \#1$  or on the rising edge of  $\text{DATACLK} \#2$ . The LSB will be valid on the falling edge of  $\text{DATACLK} \#16$  or the rising edge of  $\text{DATACLK} \#17$ . After the rising edge of  $\text{DATACLK} \#17$  the  $\text{DATA}$  pin will take on the value of the  $\text{TAG}$  pin that occurred at the rising edge of  $\text{DATACLK} \#1$ . A minimum of 17 clock pulses are required if the data is captured on falling clock edges.

Using the highest frequency permitted for  $\text{DATACLK}$  (20MHz), shifting the data out after the conversion will not degrade the 200kHz throughput. This method minimizes the possible external disturbances that can occur while a conversion is in progress and will yield the best performance.

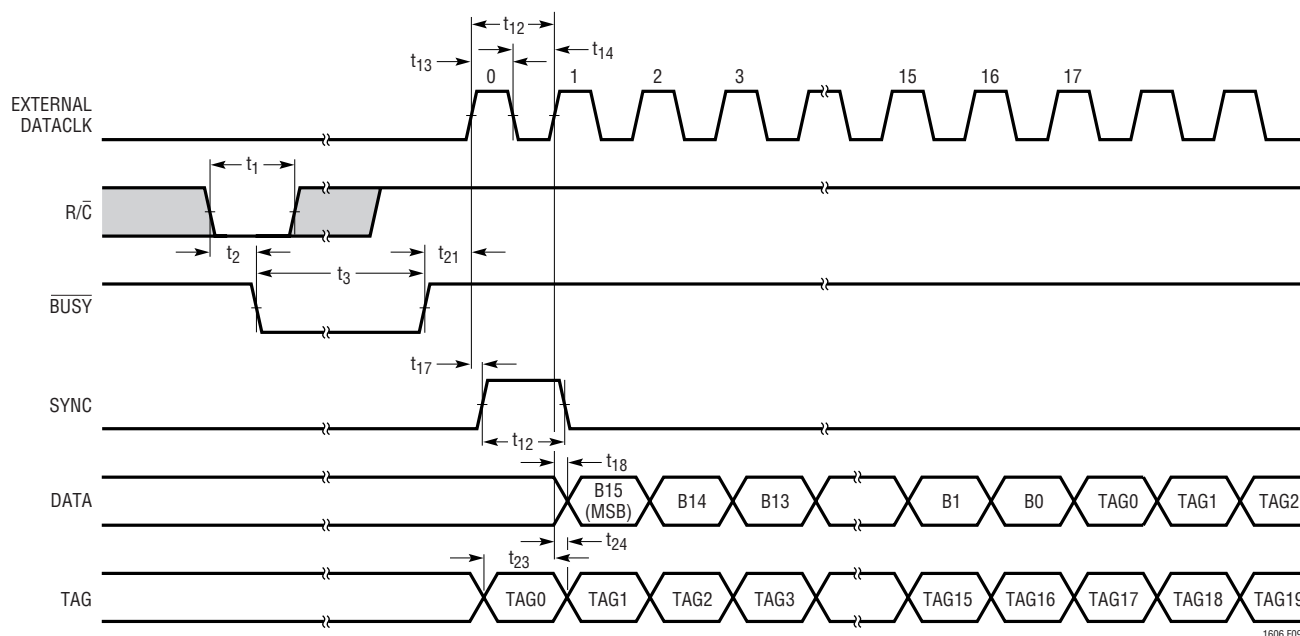

Figure 9. Conversion and Read Timing Using an External Discontinuous Data Clock ( $\overline{\text{EXT/INT}}$  Tied High,  $\overline{\text{CS}}$  Tied Low). Read Conversion Result After the Conversion

## APPLICATIONS INFORMATION

### External Data Clock Data Read After the Conversion

Figure 10 shows how the result from the current conversion can be read out after the conversion has been completed. The externally supplied data clock is running continuously.  $\overline{CS}$  and  $R/\overline{C}$  are first used together to initiate a conversion and then  $\overline{CS}$  is used to read the result. The conversion starts on the falling edge of  $\overline{CS}$  with  $R/\overline{C}$  low. Both  $\overline{CS}$  and  $R/\overline{C}$  should be returned high within  $1.2\mu\text{s}$  to prevent the transition from disturbing the conversion. After the conversion has been completed ( $\overline{BUSY}$  returning high), a pulse on the SYNC pin will be generated after the first rising edge of DATACLK #1 that occurs after  $\overline{CS}$  goes low ( $R/\overline{C}$  high). The SYNC output can be captured on the falling edge of DATACLK #1 or on the rising edge of DATACLK #2. After the rising edge of DATACLK #2, the SYNC output will go low and the MSB will be clocked out on the DATA pin. This bit can be latched on the falling edge of DATACLK #2 or on the rising edge of DATACLK #3. The LSB will be valid on the falling edge of DATACLK #17 or the rising edge of DATACLK #18. After the rising edge of DATACLK #18 the DATA pin will take on the value of the TAG pin that occurred at the rising edge of DATACLK #2.

Using the highest frequency permitted for DATACLK (20MHz), shifting the data out after the conversion will not degrade the 200kHz throughput.

### External Discontinuous Data Clock Data Read During the Conversion

Figure 11 shows how the result from the previous conversion can be read out during the current conversion. The externally supplied data clock is running discontinuously.  $R/\overline{C}$  is used to initiate a conversion with  $\overline{CS}$  tied low. The conversion starts on the falling edge of  $R/\overline{C}$ .  $R/\overline{C}$  should be returned high within  $1.2\mu\text{s}$  to prevent the transition from disturbing the conversion. A pulse on the SYNC pin will be generated on rising edge of DATACLK #0. The SYNC output can be captured on the falling edge of DATACLK #0 or on the rising edge of DATACLK #1. After the rising edge of DATACLK #1, the SYNC output will go low and the MSB will be clocked out on the DATA pin. This bit can be latched on the falling edge of DATACLK #1 or on the rising edge of DATACLK #2. The LSB will be valid on the falling edge of DATACLK #16. Another clock pulse would be needed if the LSB is captured on a rising edge. A minimum of 17 clock pulses are required if the data is captured on falling clock edges.

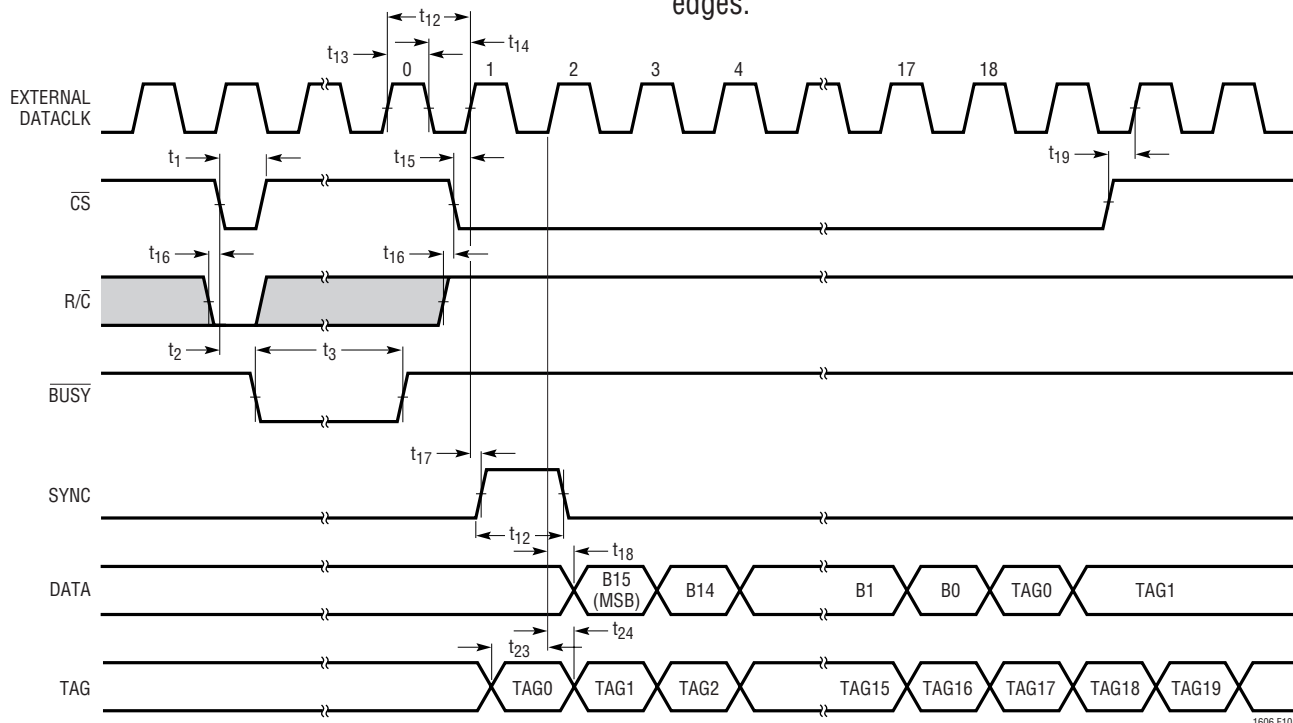

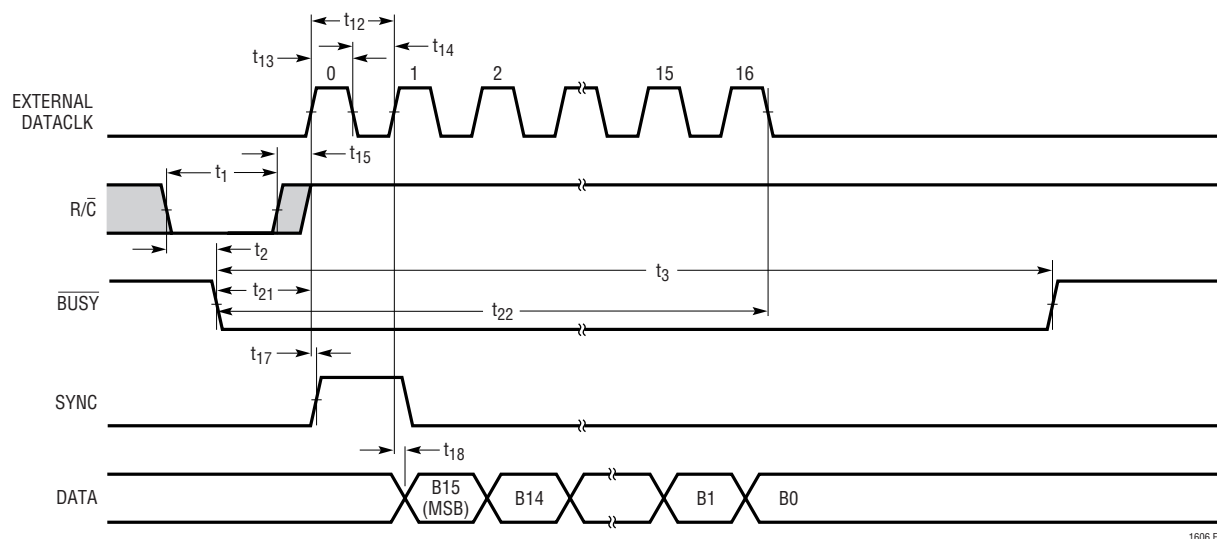

Figure 10. Conversion and Read Timing with External Clock (EXT/INT Tied High). Read After Conversion

1609fa

## APPLICATIONS INFORMATION

**Figure 11. Conversion and Read Timing Using a Discontinuous Data Clock (EXT/INT Tied High,  $\overline{CS}$  Tied Low). Read Previous Conversion Result During the Conversion. For Best Performance, Complete Read in Less Than 1.2 $\mu$ s**

To minimize the possible external disturbances that can occur while a conversion is in progress, the data needs to be shifted out within 1.2 $\mu$ s from the start of the conversion. Using the maximum data clock frequency of 20MHz will ensure this condition is met.

### External Data Clock Data Read During the Conversion

Figure 12 shows how the result from the previous conversion can be read out during the current conversion. The externally supplied data clock is running continuously.  $\overline{CS}$  and  $\overline{R/C}$  are used to initiate a conversion and read the data from the previous conversion. The conversion starts on the falling edge of  $\overline{CS}$  after  $\overline{R/C}$  is low. A pulse on the SYNC pin will be generated on the first rising edge of DATACLK #1 after  $\overline{R/C}$  has returned high. The SYNC output can be captured on the falling edge of DATACLK #1 or on the rising edge of DATACLK #2. After the rising edge of DATACLK #2 the SYNC output will go low and the MSB will be clocked out on the DATA pin. This bit can be latched on the falling edge of DATACLK #2 or on the rising edge of DATACLK #3. The LSB will be valid on the falling edge of DATACLK #17 or the rising edge of DATACLK #18. After the rising edge of DATACLK #18 the DATA pin will take on the value of the TAG pin that occurred at the rising edge of DATACLK #2.

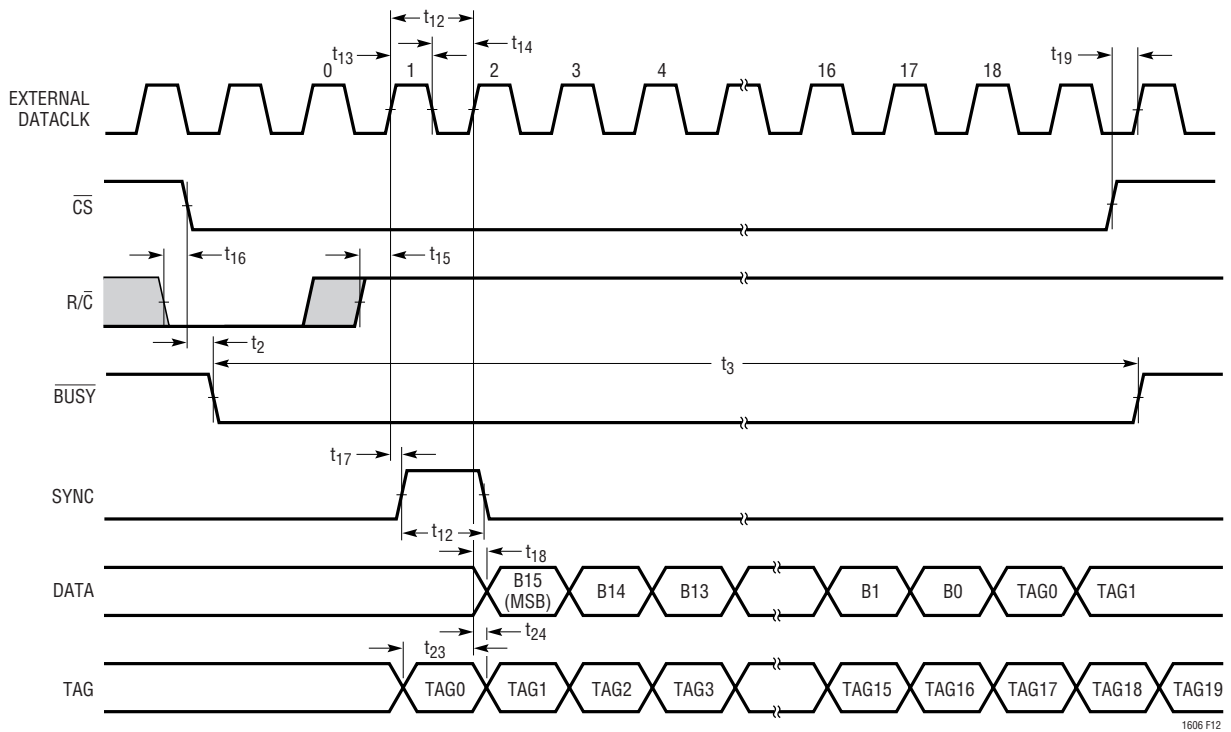

To minimize the possible external disturbances that can occur while a conversion is in progress, the data needs to be shifted out within 1.2 $\mu$ s from the start of the conversion. Using the maximum data clock frequency of 20MHz will ensure this condition is met. Since there is no throughput penalty for clocking the data out after the conversion, clocking the data out during the conversion is not recommended.

### Use of the TAG Input

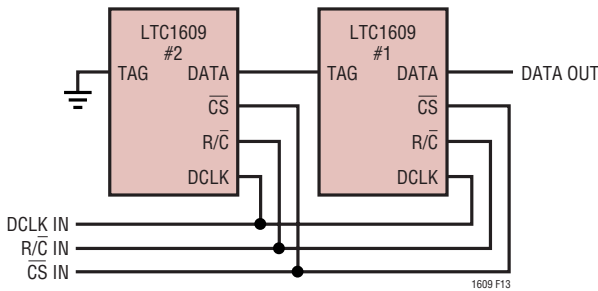

The TAG input pin is used to daisy-chain multiple converters. This is useful for applications where hardware constraints may limit the number of lines needed to interface to a large number of converters. This mode of operation works only using the external clock method of shifting out the data.

Figure 13 shows how this feature can be used.  $\overline{R/C}$ ,  $\overline{CS}$  and the DATACLK are tied together on both LTC1609s.  $\overline{CS}$  can be grounded if a discontinuous data clock is used. A falling edge on  $\overline{R/C}$  will allow both LTC1609s to capture their respective analog input signals simultaneously. Once the conversion has been completed the external data clock DCLK is started. The MSB from device #1 will be valid after the rising edge of DCLK #1. Once the LSB from device #1 has been shifted out on the rising edge of DCLK #16, a null

## APPLICATIONS INFORMATION

**Figure 12. Conversion and Read Timing Using an External Data Clock (EXT/INT Tied High). Read Previous Conversion Result During the Conversion. For Best Performance, Complete Read in Less Than 1.2 $\mu$ s**

**Figure 13. Two LTC1609s Cascaded Together Using the TAG Input**

bit will be shifted out on the following clock pulse before the MSB from device #2 becomes available (Figure 14). The reason for this is the MSB from device #2 will not be valid soon enough to meet the minimum setup time of device #1's TAG input. A minimum of 34 clock pulses are needed to shift out the results from both LTC1609s assuming the data is captured on the falling clock edge. Using the highest frequency permitted for DATACLK (20MHz), a 200kHz throughput can still be achieved.

## APPLICATIONS INFORMATION

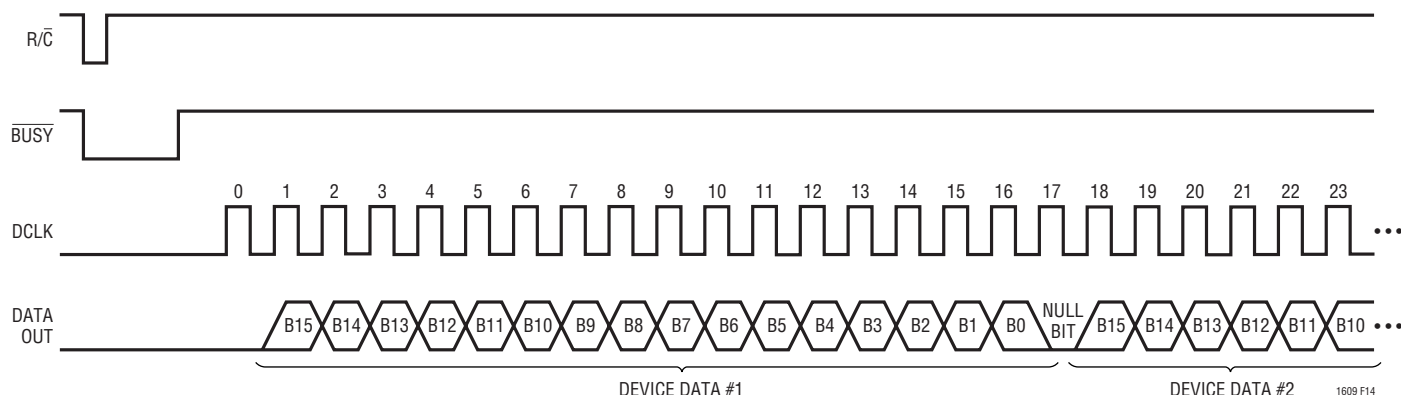

Figure 14. Data Output from Cascading Two ( $\overline{CS}$  = Low, TAG (#2) = Low) LTC1609s Together

### Output Data Format

The  $\overline{SB/BTC}$  pin controls the format of the serial digital output word. With the pin tied high the format is straight binary. With the pin tied low the data format is two's complement. See Table 1c.

### Board Layout, Power Supplies and Decoupling

Wire wrap boards are not recommended for high resolution or high speed A/D converters. To obtain the best performance from the LTC1609, a printed circuit board is required. Layout for the printed circuit board should ensure the digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC. The analog input should be screened by AGND.

Pay particular attention to the design of the analog and digital ground planes. Placing the bypass capacitor as close as possible to the  $V_{DIG}$  and  $V_{ANA}$  pins, the REF pin and reference buffer output is very important. Low impedance common returns for these bypass capacitors are essential to low noise operation of the ADC, and the foil width for these tracks should be as wide as possible. Also, since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedance as much as possible. The digital output latches and the onboard sampling clock have been placed on the digital ground plane. The two ground planes are tied together at the power supply ground connection.

A "postage stamp" (1.6in  $\times$  1.5in) evaluation board is available and allows fast in-situ evaluation of the LTC1609. See Figures 15a through 15d, inclusive.
