

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Email & Skype: info@chipsmall.com Web: www.chipsmall.com

Address: A1208, Overseas Decoration Building, #122 Zhenhua RD., Futian, Shenzhen, China

FEATURES

- 70dB SNR
- 90dB SFDR
- Low Power: 650mW/616mW/567mW Total
- Single 1.8V Supply
- DDR LVDS Outputs
- Easy-to-Drive 1.5V_{P-P} Input Range
- 1.25GHz Full Power Bandwidth S/H
- Optional Clock Duty Cycle Stabilizer
- Low Power Sleep and Nap Modes
- Serial SPI Port for Configuration
- Pin-Compatible 12-Bit Versions
- 64-Pin (9mm × 9mm) QFN Package

APPLICATIONS

- Communications
- Cellular Basestations
- Software Defined Radios
- Medical Imaging
- High Definition Video
- Testing and Measurement Instruments

DESCRIPTION

The **LTC[®]2157-14/LTC2156-14/LTC2155-14** are 2-channel simultaneous sampling 250Msps/210Msps/170Msps 14-bit A/D converters designed for digitizing high frequency, wide dynamic range signals. They are perfect for demanding communications applications with AC performance that includes 70dB SNR and 90dB spurious free dynamic range (SFDR). The 1.25GHz input bandwidth allows the ADC to undersample high frequencies with good performance. The latency is only six clock cycles.

DC specs include $\pm 0.85\text{LSB INL (typ)}$, $\pm 0.25\text{LSB DNL (typ)}$ and no missing codes over temperature. The transition noise is $1.82\text{LSB}_{\text{RMS}}$.

The digital outputs are double data rate (DDR) LVDS.

The **ENC⁺** and **ENC⁻** inputs can be driven differentially with a sine wave, PECL, LVDS, TTL, or CMOS inputs. An optional clock duty cycle stabilizer allows high performance at full speed for a wide range of clock duty cycles.

t_{DO}	SCK Falling to SDO Valid	Readback Mode, $C_{SDO} = 20\text{pF}$, $R_{PULLUP} = 2\text{k}$	●			125	ns

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All voltage values are with respect to GND with GND and OGDN shorted (unless otherwise noted).

Note 3: When these pin voltages are taken below GND or above V_{DD} , they will be clamped by internal diodes. This product can handle input currents of greater than 100mA below GND or above V_{DD} without latchup.

Note 4: When these pin voltages are taken below GND they will be clamped by internal diodes. When these pin voltages are taken above V_{DD} they will not be clamped by internal diodes. This product can handle input currents of greater than 100mA below GND without latchup.

Note 5: $V_{DD} = OV_{DD} = 1.8\text{V}$, $f_{SAMPLE} = 250\text{MHz}$ (LTC2157), 210MHz (LTC2156), or 170MHz (LTC2155), differential $ENC^+/ENC^- = 2V_{P-P}$ sine wave, input range = $1.5V_{P-P}$ with differential drive, unless otherwise noted.

Note 6: Integral nonlinearity is defined as the deviation of a code from a best fit straight line to the transfer curve. The deviation is measured from the center of the quantization band.

Note 7: Offset error is the offset voltage measured from -0.5LSB when the output code flickers between 00 0000 0000 0000 and 11 1111 1111 1111 in 2's complement output mode.

Note 8: Guaranteed by design, not subject to test.

Note 9: Recommended operating conditions.

PIN FUNCTIONS

V_{DD} (Pins 1, 2, 15, 16, 17, 64): 1.8V Analog Power Supply. Bypass to ground with 0.1μF ceramic capacitors. Pins 1, 2, 64 can share a bypass capacitor. Pins 15, 16, 17 can share a bypass capacitor.

GND (Pins 3, 6, 9, 11, 14, 18, 21, 58, Exposed Pad Pin 65): ADC Power Ground. The exposed pad must be soldered to the PCB ground.

A_{INA}⁺ (Pin 4): Positive Differential Analog Input for Channel A.

A_{INA}⁻ (Pin 5): Negative Differential Analog Input for Channel A.

SENSE (Pin 7): Reference Programming Pin. Connecting SENSE to V_{DD} selects the internal reference and a ±0.75V input range. An external reference between 1.2V and 1.3V applied to SENSE selects an input range of ±0.6 × V_{SENSE}.

V_{REF} (Pin 8): Reference Voltage Output. Bypass to ground with a 2.2μF ceramic capacitor. Nominally 1.25V.

V_{CM} (Pin 10): Common Mode Bias Output; nominally equal to 0.435 • V_{DD}. V_{CM} should be used to bias the common mode of the analog inputs. Bypass to ground with a 0.1μF ceramic capacitor.

A_{INB}⁻ (Pin 12): Negative Differential Analog Input for Channel B.

A_{INB}⁺ (Pin 13): Positive Differential Analog Input for Channel B.

ENC⁺ (Pin 19): Encode Input. Conversion starts on the rising edge.

ENC⁻ (Pin 20): Encode Complement Input. Conversion starts on the falling edge.

OGND (Pins 33, 48): Output Driver Ground.

OV_{DD} (Pins 32, 49): 1.8V Output Driver Supply. Bypass each pin to ground with separate 0.1μF ceramic capacitors.

SDO (Pin 59): Serial Interface Data Output. In serial programming mode, (PAR/ $\overline{\text{SER}}$ = 0V), SDO is the optional serial interface data output. Data on SDO is read back from the mode control registers and can be latched on the falling edge of SCK. SDO is an open-drain N-channel MOSFET output that requires an external 2k pull-up resistor from 1.8V to 3.3V. If readback from the mode control registers is not needed, the pull-up resistor is not necessary and SDO can be left unconnected.

SDI (Pin 60): Serial Interface Data Input. In serial programming mode, (PAR/ $\overline{\text{SER}}$ = 0V), SDI is the serial interface data input. Data on SDI is clocked into the mode control registers on the rising edge of SCK. In the parallel programming mode (PAR/ $\overline{\text{SER}}$ = V_{DD}), SDI selects 3.5mA or 1.75mA LVDS output current (see Table 2). SDI can be driven with 1.8V to 3.3V logic.

SCK (Pin 61): Serial Interface Clock Input. In serial programming mode, (PAR/ $\overline{\text{SER}}$ = 0V), SCK is the serial interface clock input. In the parallel programming mode (PAR/ $\overline{\text{SER}}$ = V_{DD}), SCK can be used to place the part in the low power sleep mode (see Table 2). SCK can be driven with 1.8V to 3.3V logic.

$\overline{\text{CS}}$ (Pin 62): Serial Interface Chip Select Input. In serial programming mode, (PAR/ $\overline{\text{SER}}$ = 0V), $\overline{\text{CS}}$ is the serial interface chip select input. When $\overline{\text{CS}}$ is low, SCK is enabled for shifting data on SDI into the mode control registers. In the parallel programming mode (PAR/ $\overline{\text{SER}}$ = V_{DD}), $\overline{\text{CS}}$ controls the clock duty cycle stabilizer (see Table 2). $\overline{\text{CS}}$ can be driven with 1.8V to 3.3V logic.

PAR/ $\overline{\text{SER}}$ (Pin 63): Programming Mode Selection Pin. Connect to ground to enable the serial programming mode where $\overline{\text{CS}}$, SCK, SDI, SDO become a serial interface that control the A/D operating modes. Connect to V_{DD} to enable the parallel programming mode where $\overline{\text{CS}}$, SCK, SDI become parallel logic inputs that control a reduced set of the A/D operating modes. PAR/ $\overline{\text{SER}}$ should be connected directly to ground or the V_{DD} of the part and not be driven by a logic signal.

PIN FUNCTIONS

LVDS Outputs

The following pins are differential LVDS outputs. The output current level is programmable. There is an optional internal 100Ω termination resistor between the pins of each LVDS output pair.

OF⁻/OF⁺ (Pins 22/23): Over/Underflow Digital Output. OF⁺ is high when an overflow or underflow has occurred. The overflows for channel A and channel B are multiplexed together.

D_{B0_1}⁻/D_{B0_1}⁺ to D_{B12_13}⁻/D_{B12_13}⁺ (Pins 24/25, 26/27, 28/29, 30/31, 34/35, 36/37, 38/39): Channel B Double Data Rate Digital Outputs. Two data bits are multiplexed onto each differential output pair. The even data bits (DB0, DB2, DB4, DB6, DB8, DB10, DB12) appear when CLKOUT⁺

is low. The odd data bits (DB1, DB3, DB5, DB7, DB9, DB11, DB13) appear when CLKOUT⁺ is high.

CLKOUT⁻/CLKOUT⁺ (Pins 40/41): Data Output Clock. The digital outputs normally transition at the same time as the falling and rising edges of CLKOUT⁺. The phase of CLKOUT⁺ can also be delayed relative to the digital outputs by programming the mode control registers.

D_{A0_1}⁻/D_{A0_1}⁺ to D_{A12_13}⁻/D_{A12_13}⁺ (Pins 42/43, 44/45, 46/47, 50/51, 52/53, 54/55, 56/57): Channel A Double Data Rate Digital Outputs. Two data bits are multiplexed onto each differential output pair. The even data bits (DA0, DA2, DA4, DA6, DA8, DA10, DA12) appear when CLKOUT⁺ is low. The odd data bits (DA1, DA3, DA5, DA7, DA9, DA11, DA13) appear when CLKOUT⁺ is high.

APPLICATIONS INFORMATION

CONVERTER OPERATION

The LTC2157-14/LTC2156-14/LTC2155-14 are two-channel, 14-bit 250MSPS/210MSPS/170MSPS A/D converters that are powered by a single 1.8V supply. The analog inputs must be driven differentially. The encode inputs should be driven differentially for optimal performance. The digital outputs are double data rate LVDS. Additional features can be chosen by programming the mode control registers through a serial SPI port.

ANALOG INPUT

The analog inputs are differential CMOS sample-and-hold circuits (Figure 2). The inputs must be driven differentially around a common mode voltage set by the V_{CM} output pin, which is nominally $0.435 \cdot V_{DD}$. For the 1.5V input range, the inputs should swing from $V_{CM} - 0.375V$ to $V_{CM} + 0.375V$. There should be 180° phase difference between the inputs.

The two channels are simultaneously sampled by a shared encode circuit.

Figure 2. Equivalent Input Circuit. Only One of Two Analog Channels Is Shown

INPUT DRIVE CIRCUITS

Input Filtering

If possible, there should be an RC lowpass filter right at the analog inputs. This lowpass filter isolates the drive circuitry from the A/D sample-and-hold switching, and also limits wide band noise from the drive circuitry. Figure 3 shows an example of an input RC filter. The RC component values should be chosen based on the application's specific input frequency.

Transformer-Coupled Circuits

Figure 3 shows the analog input being driven by an RF transformer with the common mode supplied through a pair of resistors via the V_{CM} pin.

At higher input frequencies a transmission line balun transformer (Figures 4 and 5) has better balance, resulting in lower A/D distortion.

Figure 3. Analog Input Circuit Using a Transformer. Recommended for Input Frequencies from 5MHz to 70MHz

Figure 4. Recommended Front-End Circuit for Input Frequencies from 15MHz to 150MHz

APPLICATIONS INFORMATION

Figure 5. Recommended Front-End Circuit for Input Frequencies from 150MHz to 900MHz

Figure 6. Front-End Circuit Using a High Speed Differential Amplifier

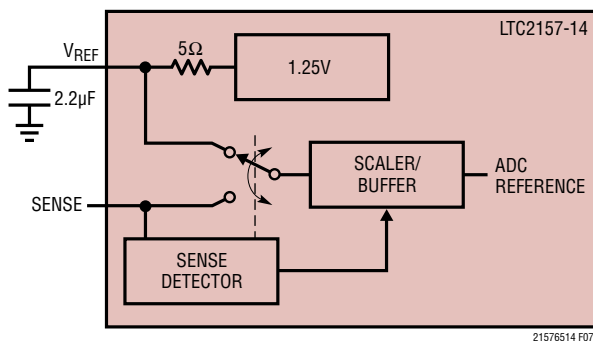

Figure 7. Reference Circuit

Amplifier Circuits

Figure 6 shows the analog input being driven by a high speed differential amplifier. The output of the amplifier is AC coupled to the A/D so the amplifier's output common mode voltage can be optimally set to minimize distortion.

At very high frequencies an RF gain block will often have lower distortion than a differential amplifier. If the gain block is single-ended, then a transformer circuit (Figures 3 and 5) should convert the signal to differential before driving the A/D. The A/D cannot be driven single-ended.

Reference

The LTC2157-14/LTC2156-14/LTC2155-14 has an internal 1.25V voltage reference. For a 1.5V input range with internal reference, connect SENSE to V_{DD} . For a 1.5V input range with an external reference, apply a 1.25V reference voltage to SENSE (Figure 7).

Encode Input

The signal quality of the encode inputs strongly affects the A/D noise performance. The encode inputs should be treated as analog signals—do not route them next to digital traces on the circuit board.

The encode inputs are internally biased to 1.2V through 10k equivalent resistance (Figure 8). If the common mode of the driver is within 1.1V to 1.5V, it is possible to drive the encode inputs directly. Otherwise a transformer or coupling capacitors are needed (Figures 9 and 10). The maximum (peak) voltage of the input signal should never exceed $V_{DD} + 0.1V$ or go below $-0.1V$.

Figure 8. Equivalent Encode Input Circuit

APPLICATIONS INFORMATION

Clock Duty Cycle Stabilizer

For good performance the encode signal should have a 50% ($\pm 5\%$) duty cycle. If the optional clock duty cycle stabilizer circuit is enabled, the encode duty cycle can vary from 30% to 70% and the duty cycle stabilizer will maintain a constant 50% internal duty cycle. The duty cycle stabilizer is enabled via SPI Register A2 (see Table 3) or by \overline{CS} in parallel programming mode.

For applications where the sample rate needs to be changed quickly, the clock duty cycle stabilizer can be disabled. In this cases care should be taken to make the clock a 50% ($\pm 5\%$) duty cycle.

DIGITAL OUTPUTS

The digital outputs are double data rate LVDS signals. Two data bits are multiplexed and output on each differential

output pair. There are seven LVDS output pairs for channel A (DA0_1+/DA0_1- through DA12_13-/DA12_13+) and seven pairs for channel B (DB0_1+/DB0_1- through DB12_13-/DB12_13+). Overflow (OF+/OF-) and the data output clock (CLKOUT+/CLKOUT-) each have an LVDS output pair. Note that overflow for both channels is multiplexed onto the OF+/OF- output pair.

By default the outputs are standard LVDS levels: 3.5mA output current and a 1.25V output common mode voltage. An external 100 Ω differential termination resistor is required for each LVDS output pair. The termination resistors should be located as close as possible to the LVDS receiver.

The outputs are powered by OV_{DD} and $OGND$ which are isolated from the A/D core power and ground.

Figure 9. Sinusoidal Encode Drive

Figure 10. PECL or LVDS Encode Drive

APPLICATIONS INFORMATION

Programmable LVDS Output Current

The default output driver current is 3.5mA. This current can be adjusted by serially programming mode control register A3 (see Table 3). Available current levels are 1.75mA, 2.1mA, 2.5mA, 3mA, 3.5mA, 4mA and 4.5mA.

Optional LVDS Driver Internal Termination

In most cases, using just an external 100Ω termination resistor will give excellent LVDS signal integrity. In addition, an optional internal 100Ω termination resistor can be enabled by serially programming mode control register A3. The internal termination helps absorb any reflections caused by imperfect termination at the receiver. When the internal termination is enabled, the output driver current is doubled to maintain the same output voltage swing.

Overflow Bit

The overflow output bit (OF) outputs a logic high when the analog input is either overranged or underranged. The overflow bit has the same pipeline latency as the data bits. The OF output is double data rate; when CLKOUT⁺ is low,

channel A's overflow is available; when CLKOUT⁺ is high, channel B's overflow is available.

Phase Shifting the Output Clock

To allow adequate set-up and hold time when latching the output data, the CLKOUT⁺ signal may need to be phase shifted relative to the data output bits. Most FPGAs have this feature; this is generally the best place to adjust the timing.

Alternatively, the ADC can also phase shift the CLKOUT⁺/CLKOUT⁻ signals by serially programming mode control register A2. The output clock can be shifted by 0°, 45°, 90°, or 135°. To use the phase shifting feature the clock duty cycle stabilizer must be turned on. Another control register bit can invert the polarity of CLKOUT⁺ and CLKOUT⁻, independently of the phase shift. The combination of these two features enables phase shifts of 45° up to 315° (Figure 11).

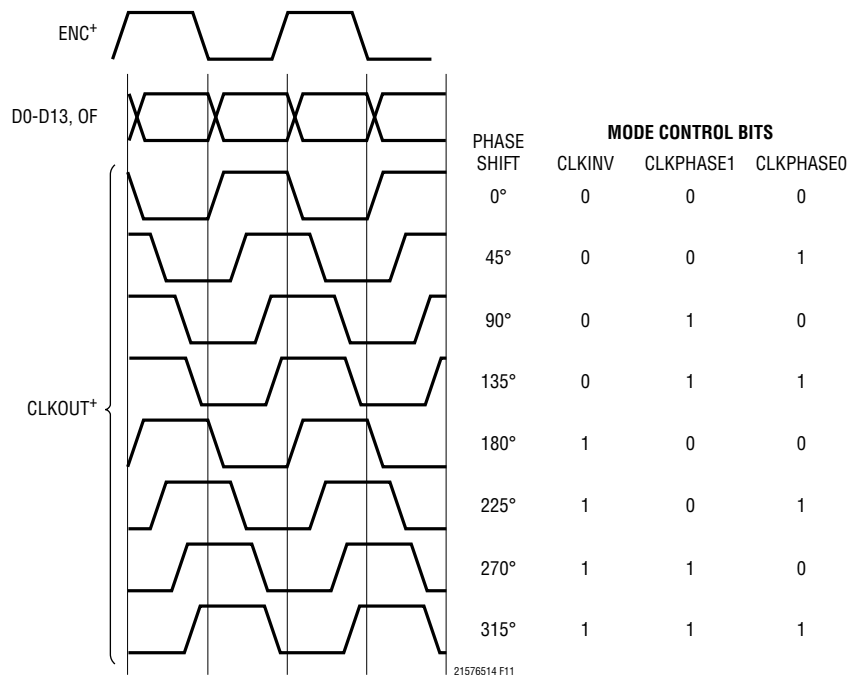

Figure 11. Phase Shifting CLKOUT

APPLICATIONS INFORMATION

DATA FORMAT

Table 1 shows the relationship between the analog input voltage, the digital data output bits and the overflow bit. By default the output data format is offset binary. The 2's complement format can be selected by serially programming mode control register A4.

Table 1. Output Codes vs Input Voltage

$A_{IN}^+ - A_{IN}^-$ (1.5V Range)	OF	D13-D0 (OFFSET BINARY)	D13-D0 (2's COMPLEMENT)
>0.75 V	1	11 1111 1111 1111	01 1111 1111 1111
+0.75V	0	11 1111 1111 1111	01 1111 1111 1111
+0.749908V	0	11 1111 1111 1110	01 1111 1111 1110
+0.0000915V	0	10 0000 0000 0001	00 0000 0000 0001
+0.000000V	0	10 0000 0000 0000	00 0000 0000 0000
-0.0000915V	0	01 1111 1111 1111	11 1111 1111 1111
-0.0001831V	0	01 1111 1111 1110	11 1111 1111 1110
-0.7499084V	0	00 0000 0000 0001	10 0000 0000 0001

< -0.75V	1	00 0000 0000 0000	10 0000 0000 0000

Digital Output Randomizer

Interference from the A/D digital outputs is sometimes unavoidable. Digital interference may be from capacitive or inductive coupling or coupling through the ground plane. Even a tiny coupling factor can cause unwanted tones in the ADC output spectrum. By randomizing the digital output before it is transmitted off chip, these unwanted tones can be randomized which reduces the unwanted tone amplitude.

The digital output is randomized by applying an exclusive-OR logic operation between the LSB and all other data output bits. To decode, the reverse operation is applied—an exclusive-OR operation is applied between the LSB and all other bits. The LSB, OF and CLKOUT outputs are not affected. The output randomizer is enabled by serially programming mode control register A4.

Figure 12. Functional Equivalent of Digital Output Randomizer

Figure 13. Decoding a Randomized Digital Output Signal

APPLICATIONS INFORMATION

Alternate Bit Polarity

Another feature that may reduce digital feedback on the circuit board is the alternate bit polarity mode. When this mode is enabled, all of the odd bits (D1, D3, D5, D7, D9, D11, D13) are inverted before the output buffers. The even bits (D0, D2, D4, D6, D8, D10, D12), OF and CLKOUT are not affected. This can reduce digital currents in the circuit board ground plane and reduce digital noise, particularly for very small analog input signals.

The digital output is decoded at the receiver by inverting the odd bits (D1, D3, D5, D7, D9, D11, D13.) The alternate bit polarity mode is independent of the digital output randomizer—either both or neither function can be on at the same time. The alternate bit polarity mode is enabled by serially programming mode control register A4.

Digital Output Test Patterns

To allow in-circuit testing of the digital interface to the A/D, there are several test modes that force the A/D data outputs (OF, D13 to D0) to known values:

All 1s: All outputs are 1

All 0s: All outputs are 0

Alternating: Outputs change from all 1s to all 0s on alternating samples

Checkerboard: Outputs change from 101010101010101 to 010101010101010 on alternating samples.

The digital output test patterns are enabled by serially programming mode control register A4. When enabled, the test patterns override all other formatting modes: 2's complement, randomizer, alternate-bit polarity.

Output Disable

The digital outputs may be disabled by serially programming mode control register A3. All digital outputs including OF and CLKOUT are disabled. The high impedance disabled state is intended for long periods of inactivity, it is not designed for multiplexing the data bus between multiple converters.

Sleep Mode

The A/D may be placed in sleep mode to conserve power. In sleep mode the entire A/D converter is powered down, resulting in $< 5\text{mW}$ power consumption. If the encode input signal is not disabled the power consumption will be higher (up to 5mW at 250MSPS). Sleep mode is enabled by mode control register A1 (serial programming mode), or by SCK (parallel programming mode).

In the serial programming mode it is also possible to disable channel B while leaving channel A in normal operation.

The amount of time required to recover from sleep mode depends on the size of the bypass capacitor on V_{REF} . For the suggested value in Figure 1, the A/D will stabilize after $0.1\text{ms} + 2500 \cdot t_p$ where t_p is the period of the sampling clock.

Nap Mode

In nap mode the A/D core is powered down while the internal reference circuits stay active, allowing faster wakeup. Recovering from nap mode requires at least 100 clock cycles. Nap mode is enabled by setting register A1 in the serial programming mode.

Wake-up time from nap mode is guaranteed only if the clock is kept running, otherwise sleep mode Wake-up conditions apply.

DEVICE PROGRAMMING MODES

The operating modes of the LTC215X-14 can be programmed by either a parallel interface or a simple serial interface. The serial interface has more flexibility and can program all available modes. The parallel interface is more limited and can only program some of the more commonly used modes.

Parallel Programming Mode

To use the parallel programming mode, $\overline{\text{PAR}}/\overline{\text{SER}}$ should be tied to V_{DD} . The $\overline{\text{CS}}$, SCK and SDI pins are binary logic inputs that set certain operating modes. These pins can be tied to V_{DD} or ground, or driven by 1.8V, 2.5V, or 3.3V CMOS logic. Table 2 shows the modes set by $\overline{\text{CS}}$, SCK and SDI.

APPLICATIONS INFORMATION

Table 2. Parallel Programming Mode Control Bits (PAR/ $\overline{\text{SER}}$ = V_{DD})

PIN	DESCRIPTION
$\overline{\text{CS}}$	Clock Duty Cycle Stabilizer Control Bit 0 = Clock Duty Cycle Stabilizer Off 1 = Clock Duty Cycle Stabilizer On
SCK	Power Down Control Bit 0 = Normal Operation 1 = Sleep Mode (entire ADC is powered down)
SDI	LVDS Current Selection Bit 0 = 3.5mA LVDS Current Mode 1 = 1.75mA LVDS Current Mode

Serial Programming Mode

To use the serial programming mode, PAR/ $\overline{\text{SER}}$ should be tied to ground. The $\overline{\text{CS}}$, SCK, SDI and SDO pins become a serial interface that program the A/D control registers. Data is written to a register with a 16-bit serial word. Data can also be read back from a register to verify its contents.

Serial data transfer starts when $\overline{\text{CS}}$ is taken low. The data on the SDI pin is latched at the first sixteen rising edges of SCK. Any SCK rising edges after the first sixteen are ignored. The data transfer ends when $\overline{\text{CS}}$ is taken high again.

The first bit of the 16-bit input word is the R/ $\overline{\text{W}}$ bit. The next seven bits are the address of the register (A6:A0). The final eight bits are the register data (D7:D0).

If the R/ $\overline{\text{W}}$ bit is low, the serial data (D7:D0) will be written to the register set by the address bits (A6:A0). If the R/ $\overline{\text{W}}$ bit is high, data in the register set by the address bits (A6:A0) will be read back on the SDO pin (see the Timing Diagrams). During a readback command the register is not updated and data on SDI is ignored.

The SDO pin is an open-drain output that pulls to ground with a 200 Ω impedance. If register data is read back through SDO, an external 2k pull-up resistor is required. If serial data is only written and readback is not needed, then SDO can be left floating and no pull-up resistor is needed. Table 3 shows a map of the mode control registers.

Software Reset

If serial programming is used, the mode control registers should be programmed as soon as possible after the power supplies turn on and are stable. The first serial command must be a software reset which will reset all register data bits to logic 0. To perform a software reset it is necessary to write 1 in register A0 (Bit D7). After the reset is complete, Bit D7 is automatically set back to zero. This register is write-only.

GROUNDING AND BYPASSING

The LTC215X-14 requires a printed circuit board with a clean unbroken ground plane in the first layer beneath the ADC. A multilayer board with an internal ground plane is recommended. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC.

High quality ceramic bypass capacitors should be used at the V_{DD} , OV_{DD} , V_{CM} , V_{REF} pins. Bypass capacitors must be located as close to the pins as possible. Size 0402 ceramic capacitors are recommended. The traces connecting the pins and bypass capacitors must be kept short and should be made as wide as possible.

The analog inputs, encode signals, and digital outputs should not be routed next to each other. Ground fill and grounded vias should be used as barriers to isolate these signals from each other.

HEAT TRANSFER

Most of the heat generated by the LTC215X-14 is transferred from the die through the bottom-side exposed pad and package leads onto the printed circuit board. For good electrical and thermal performance, the exposed pad must be soldered to a large grounded pad on the PC board. This pad should be connected to the internal ground planes by an array of vias.

APPLICATIONS INFORMATION

Table 3. Serial Programming Mode Register Map (PAR/ $\overline{\text{SER}}$ = GND). X Indicates Unused Bit

REGISTER A0: RESET REGISTER (ADDRESS 00h) Write Only

D7	D6	D5	D4	D3	D2	D1	D0
RESET	X	X	X	X	X	X	X

Bit 7 **RESET** Software Reset Bit
 0 = Reset Disabled
 1 = Software Reset. All mode control registers are reset to 00h. This bit is automatically set back to zero after the reset is complete.

Bits 6-0 Unused Bits
