Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

64 Mbit (4Mb x16, Boot Block) 3V Supply Flash Memory

PRELIMINARY DATA

FEATURES SUMMARY

- SUPPLY VOLTAGE
  - V_{DD} = 2.7V to 3.6V Core Power Supply
  - V_{DDQ}= 1.65V to 3.6V for Input/Output
  - V_{PP} = 12V for fast Program (optional)
- ACCESS TIME: 70, 85, 90,100ns
- PROGRAMMING TIME:
  - 10µs typical
  - Double Word Programming Option
  - Quadruple Word Programming Option
- COMMON FLASH INTERFACE
- MEMORY BLOCKS
  - Parameter Blocks (Top or Bottom location)
  - Main Blocks
- BLOCK LOCKING
  - All blocks locked at Power Up
  - Any combination of blocks can be locked
  - $\overline{WP}$ for Block Lock-Down
- SECURITY
  - 128 bit user Programmable OTP cells
  - 64 bit unique device identifier
- AUTOMATIC STAND-BY MODE
- PROGRAM and ERASE SUSPEND
- 100,000 PROGRAM/ERASE CYCLES per BLOCK
- ELECTRONIC SIGNATURE
  - Manufacturer Code: 20h
  - Top Device Code, M28W640ECT: 8848h
  - Bottom Device Code, M28W640ECB: 8849h

TABLE OF CONTENTS

SUMMARY DESCRIPTION

The M28W640EC is a 64 Mbit (4 Mbit x 16) non-volatile Flash memory that can be erased electrically at block level and programmed in-system on a Word-by-Word basis using a 2.7V to 3.6V V_{DD} supply for the circuitry and a 1.65V to 3.6V V_{DDQ} supply for the Input/Output pins. An optional 12V V_{PP} power supply is provided to speed up customer programming.

The device features an asymmetrical blocked architecture. The M28W640EC has an array of 135 blocks: 8 Parameter Blocks of 4 KWord and 127 Main Blocks of 32 KWord. M28W640ECT has the Parameter Blocks at the top of the memory address space while the M28W640ECB locates the Parameter Blocks starting from the bottom. The memory maps are shown in Figure 5, Block Addresses.

The M28W640EC features an instant, individual block locking scheme that allows any block to be locked or unlocked with no latency, enabling instant code and data protection. All blocks have three levels of protection. They can be locked and locked-down individually preventing any accidental programming or erasure. There is an additional hardware protection against program and erase. When $V_{PP} \leq V_{PPLK}$ all blocks are protected against program or erase. All blocks are locked at Power Up.

Each block can be erased separately. Erase can be suspended in order to perform either read or program in any other block and then resumed. Program can be suspended to read data in any other block and then resumed. Each block can be programmed and erased over 100,000 cycles.

The device includes a 192 bit Protection Register to increase the protection of a system design. The Protection Register is divided into a 64 bit segment and a 128 bit segment. The 64 bit segment contains a unique device number written by ST, while the second one is one-time-programmable by the user. The user programmable segment can be permanently protected. Figure 6, shows the Protection Register Memory Map.

Program and Erase commands are written to the Command Interface of the memory. An on-chip Program/Erase Controller takes care of the timings necessary for program and erase operations. The end of a program or erase operation can be detected and any error conditions identified. The command set required to control the memory is consistent with JEDEC standards.

The memory is offered in TSOP48 (12 X 20mm) and TFBGA48 (6.39 x 10.5mm, 0.75mm pitch) packages and is supplied with all the bits erased (set to '1').

SIGNAL DESCRIPTIONS

See Figure 2 Logic Diagram and Table 1,Signal Names, for a brief overview of the signals connected to this device.

Address Inputs (A0-A21). The Address Inputs select the cells in the memory array to access during Bus Read operations. During Bus Write operations they control the commands sent to the Command Interface of the internal state machine.

Data Input/Output (DQ0-DQ15). The Data I/O outputs the data stored at the selected address during a Bus Read operation or inputs a command or the data to be programmed during a Write Bus operation.

Chip Enable ($\overline{E}$). The Chip Enable input activates the memory control logic, input buffers, decoders and sense amplifiers. When Chip Enable is at $V_{IL}$and Reset is at V_{IH} the device is in active mode. When Chip Enable is at V_{IH} the memory is deselected, the outputs are high impedance and the power consumption is reduced to the stand-by level.

Output Enable ($\overline{G}$). The Output Enable controls data outputs during the Bus Read operation of the memory.

Write Enable ($\overline{W}$). The Write Enable controls the Bus Write operation of the memory's Command Interface. The data and address inputs are latched on the rising edge of Chip Enable, E, or Write Enable, $\overline{W}$, whichever occurs first.

Write Protect ($\overline{WP}$). Write Protect is an input that gives an additional hardware protection for each block. When Write Protect is at V_{IL}, the Lock-Down is enabled and the protection status of the block cannot be changed. When Write Protect is at V_{IH}, the Lock-Down is disabled and the block can be locked or unlocked. (refer to Table 7, Read Protection Register and Protection Register Lock).

Reset ($\overline{RP}$). The Reset input provides a hardware reset of the memory. When Reset is at V_{IL}, the memory is in reset mode: the outputs are high impedance and the current consumption is minimized. After Reset all blocks are in the Locked state. When Reset is at V_{IH}, the device is in normal operation. Exiting reset mode the device enters read array mode, but a negative transition of Chip Enable or a change of the address is required to ensure valid data outputs.

V_{DD} Supply Voltage. V_{DD} provides the power supply to the internal core of the memory device. It is the main power supply for all operations (Read, Program and Erase).

V_{DDQ} Supply Voltage. V_{DDQ} provides the power supply to the I/O pins and enables all Outputs to be powered independently from V_{DD}. V_{DDQ} can be tied to V_{DD} or can use a separate supply.

V_{PP} Program Supply Voltage. V_{PP} is both a control input and a power supply pin. The two functions are selected by the voltage range applied to the pin. The Supply Voltage V_{DD} and the Program Supply Voltage V_{PP} can be applied in any order.

If V_{PP} is kept in a low voltage range (0V to 3.6V) V_{PP} is seen as a control input. In this case a voltage lower than V_{PPLK} gives an absolute protection against program or erase, while $V_{PP} > V_{PP1}$ enables these functions (see Table 15, DC Characteristics for the relevant values). V_{PP} is only sampled at the beginning of a program or erase; a change in its value after the operation has started does not have any effect on Program or Erase, however for Double or Quadruple Word Program the results are uncertain.

If V_{PP} is in the range 11.4V to 12.6V it acts as a power supply pin. In this condition V_{PP} must be stable until the Program/Erase algorithm is completed (see Table 17 and 18).

V_{SS} Ground. V_{SS} is the reference for all voltage measurements.

Note: Each device in a system should have V_{DD}, V_{DDQ} and V_{PP} decoupled with a 0.1µF capacitor close to the pin. See Figure 8, AC Measurement Load Circuit. The PCB trace widths should be sufficient to carry the required V_{PP} program and erase currents.

BUS OPERATIONS

There are six standard bus operations that control the device. These are Bus Read, Bus Write, Output Disable, Standby, Automatic Standby and Reset. See Table 2, Bus Operations, for a summary.

Typically glitches of less than 5ns on Chip Enable or Write Enable are ignored by the memory and do not affect bus operations.

Read. Read Bus operations are used to output the contents of the Memory Array, the Electronic Signature, the Status Register and the Common Flash Interface. Both Chip Enable and Output Enable must be at V_{IL} in order to perform a read operation. The Chip Enable input should be used to enable the device. Output Enable should be used to gate data onto the output. The data read depends on the previous command written to the memory (see Command Interface section). See Figure 9, Read Mode AC Waveforms, and Table 16, Read AC Characteristics, for details of when the output becomes valid.

Read mode is the default state of the device when exiting Reset or after power-up.

Write. Bus Write operations write Commands to the memory or latch Input Data to be programmed. A write operation is initiated when Chip Enable and Write Enable are at V_{IL} with Output Enable at V_{IH}. Commands, Input Data and Addresses are latched on the rising edge of Write Enable or Chip Enable, whichever occurs first.

See Figures 10 and 11, Write AC Waveforms, and Tables 17 and 18, Write AC Characteristics, for details of the timing requirements.

Output Disable. The data outputs are high impedance when the Output Enable is at V_{IH}.

Standby. Standby disables most of the internal circuitry allowing a substantial reduction of the current consumption. The memory is in stand-by when Chip Enable is at V_{IH} and the device is in read mode. The power consumption is reduced to the stand-by level and the outputs are set to high impedance, independently from the Output Enable or Write Enable inputs. If Chip Enable switches to V_{IH} during a program or erase operation, the device enters Standby mode when finished.

Automatic Standby. Automatic Standby provides a low power consumption state during Read mode. Following a read operation, the device enters Automatic Standby after 150ns of bus inactivity even if Chip Enable is Low, V_{IL}, and the supply current is reduced to I_{DD1}. The data Inputs/Outputs will still output data if a bus Read operation is in progress.

Reset. During Reset mode when Output Enable is Low, V_{IL}, the memory is deselected and the outputs are high impedance. The memory is in Reset mode when Reset is at V_{IL}. The power consumption is reduced to the Standby level, independently from the Chip Enable, Output Enable or Write Enable inputs. If Reset is pulled to V_{SS} during a Program or Erase, this operation is aborted and the memory content is no longer valid.

Table 2. Bus Operations

Operation	$\overline{E}$	$\overline{G}$	$\overline{W}$	$\overline{RP}$	$\overline{WP}$	V_{PP}	DQ0-DQ15
Bus Read	V_{IL}	V_{IL}	V_{IH}	V_{IH}	X	Don't Care	Data Output
Bus Write	V_{IL}	V_{IH}	V_{IL}	V_{IH}	X	V_{DD} or V_{PPH}	Data Input
Output Disable	V_{IL}	V_{IH}	V_{IH}	V_{IH}	X	Don't Care	Hi-Z
Standby	V_{IH}	X	X	V_{IH}	X	Don't Care	Hi-Z
Reset	X	X	X	V_{IL}	X	Don't Care	Hi-Z

Note: X = V_{IL} or V_{IH}, V_{PPH} = 12V ± 5%.

COMMAND INTERFACE

All Bus Write operations to the memory are interpreted by the Command Interface. Commands consist of one or more sequential Bus Write operations. An internal Program/Erase Controller handles all timings and verifies the correct execution of the Program and Erase commands. The Program/Erase Controller provides a Status Register whose output may be read at any time during, to monitor the progress of the operation, or the Program/Erase states. See Table 3, Command Codes, for a summary of the commands and see Appendix 22, Table 32, Write State Machine Current/Next, for a summary of the Command Interface.

The Command Interface is reset to Read mode when power is first applied, when exiting from Reset or whenever V_{DD} is lower than V_{LKO}. Command sequences must be followed exactly. Any invalid combination of commands will reset the device to Read mode. Refer to Table 4, Commands, in conjunction with the text descriptions below.

Read Memory Array Command

The Read command returns the memory to its Read mode. One Bus Write cycle is required to issue the Read Memory Array command and return the memory to Read mode. Subsequent read operations will read the addressed location and output the data. When a device Reset occurs, the memory defaults to Read mode.

Read Status Register Command

The Status Register indicates when a program or erase operation is complete and the success or failure of the operation itself. Issue a Read Status Register command to read the Status Register's contents. Subsequent Bus Read operations read the Status Register at any address, until another command is issued. See Table 11, Status Register Bits, for details on the definitions of the bits.

The Read Status Register command may be issued at any time, even during a Program/Erase operation. Any Read attempt during a Program/Erase operation will automatically output the content of the Status Register.

Read Electronic Signature Command

The Read Electronic Signature command reads the Manufacturer and Device Codes and the Block Locking Status, or the Protection Register.

The Read Electronic Signature command consists of one write cycle, a subsequent read will output the Manufacturer Code, the Device Code, the Block Lock and Lock-Down Status, or the Protection and Lock Register. See Tables 5, 6 and 7 for the valid address.

Table 3. Command Codes

Hex Code	Command
01h	Block Lock confirm
10h	Program
20h	Erase
2Fh	Block Lock-Down confirm
30h	Double Word Program
40h	Program
50h	Clear Status Register
56h	Quadruple Word Program
60h	Block Lock, Block Unlock, Block Lock-Down
70h	Read Status Register
90h	Read Electronic Signature
98h	Read CFI Query
B0h	Program/Erase Suspend
C0h	Protection Register Program
D0h	Program/Erase Resume, Block Unlock confirm
FFh	Read Memory Array

Read CFI Query Command

The Read Query Command is used to read data from the Common Flash Interface (CFI) Memory Area, allowing programming equipment or applications to automatically match their interface to the characteristics of the device. One Bus Write cycle is required to issue the Read Query Command. Once the command is issued subsequent Bus Read operations read from the Common Flash Interface Memory Area. See Appendix B, Common Flash Interface, Tables 26, 27, 28, 29, 30 and 31 for details on the information contained in the Common Flash Interface memory area.

Block Erase Command

The Block Erase command can be used to erase a block. It sets all the bits within the selected block to '1'. All previous data in the block is lost. If the block is protected then the Erase operation will abort, the data in the block will not be changed and the Status Register will output the error.

Two Bus Write cycles are required to issue the command.

- The first bus cycle sets up the Erase command.

- The second latches the block address in the internal state machine and starts the Program/ Erase Controller.

If the second bus cycle is not Write Erase Confirm (D0h), Status Register bits b4 and b5 are set and the command aborts.

Erase aborts if Reset turns to V_{IL}. As data integrity cannot be guaranteed when the Erase operation is aborted, the block must be erased again.

During Erase operations the memory will accept the Read Status Register command and the Program/Erase Suspend command, all other commands will be ignored. Typical Erase times are given in Table 8, Program, Erase Times and Program/Erase Endurance Cycles.

See Appendix C, Figure 21, Erase Flowchart and Pseudo Code, for a suggested flowchart for using the Erase command.

Program Command

The memory array can be programmed word-by-word. Two bus write cycles are required to issue the Program Command.

- The first bus cycle sets up the Program command.
- The second latches the Address and the Data to be written and starts the Program/Erase Controller.

During Program operations the memory will accept the Read Status Register command and the Program/Erase Suspend command. Typical Program times are given in Table 8, Program, Erase Times and Program/Erase Endurance Cycles.

Programming aborts if Reset goes to V_{IL}. As data integrity cannot be guaranteed when the program operation is aborted, the block containing the memory location must be erased and reprogrammed.

See Appendix C, Figure 17, Program Flowchart and Pseudo Code, for the flowchart for using the Program command.

Double Word Program Command

This feature is offered to improve the programming throughput, writing a page of two adjacent words in parallel.The two words must differ only for the address A0. Programming should not be attempted when V_{PP} is not at V_{PPH}.

Three bus write cycles are necessary to issue the Double Word Program command.

- The first bus cycle sets up the Double Word Program Command.
- The second bus cycle latches the Address and the Data of the first word to be written.
- The third bus cycle latches the Address and the Data of the second word to be written and starts the Program/Erase Controller.

Read operations output the Status Register content after the programming has started. Programming aborts if Reset goes to V_{IL}. As data integrity cannot be guaranteed when the program operation is aborted, the block containing the memory location must be erased and reprogrammed.

See Appendix C, Figure 18, Double Word Program Flowchart and Pseudo Code, for the flowchart for using the Double Word Program command.

Quadruple Word Program Command

This feature is offered to improve the programming throughput, writing a page of four adjacent words in parallel.The four words must differ only for the addresses A0 and A1. Programming should not be attempted when V_{PP} is not at V_{PPH}.

Five bus write cycles are necessary to issue the Quadruple Word Program command.

- The first bus cycle sets up the Quadruple Word Program Command.
- The second bus cycle latches the Address and the Data of the first word to be written.
- The third bus cycle latches the Address and the Data of the second word to be written.
- The fourth bus cycle latches the Address and the Data of the third word to be written.
- The fifth bus cycle latches the Address and the Data of the fourth word to be written and starts the Program/Erase Controller.

Read operations output the Status Register content after the programming has started. Programming aborts if Reset goes to V_{IL}. As data integrity cannot be guaranteed when the program operation is aborted, the block containing the memory location must be erased and reprogrammed.

See Appendix C, Figure 19, Quadruple Word Program Flowchart and Pseudo Code, for the flowchart for using the Quadruple Word Program command.

Clear Status Register Command

The Clear Status Register command can be used to reset bits 1, 3, 4 and 5 in the Status Register to '0'. One bus write cycle is required to issue the Clear Status Register command.

The bits in the Status Register do not automatically return to '0' when a new Program or Erase command is issued. The error bits in the Status Register should be cleared before attempting a new Program or Erase command.

Program/Erase Suspend Command

The Program/Erase Suspend command is used to pause a Program or Erase operation. One bus write cycle is required to issue the Program/Erase command and pause the Program/Erase controller.

During Program/Erase Suspend the Command Interface will accept the Program/Erase Resume, Read Array, Read Status Register, Read Electronic Signature and Read CFI Query commands. Additionally, if the suspend operation was Erase then the Program, Double Word Program, Quadruple Word Program, Block Lock, Block Lock-Down or Protection Program commands will also be accepted. The block being erased may be protected by issuing the Block Protect, Block Lock or Protection Program commands. When the Program/Erase Resume command is issued the operation will complete. Only the blocks not being erased may be read or programmed correctly.

During a Program/Erase Suspend, the device can be placed in a pseudo-standby mode by taking Chip Enable to V_{IH}. Program/Erase is aborted if Reset turns to V_{IL}.

See Appendix C, Figure 20, Program Suspend & Resume Flowchart and Pseudo Code, and Figure 22, Erase Suspend & Resume Flowchart and Pseudo Code for flowcharts for using the Program/Erase Suspend command.

Program/Erase Resume Command

The Program/Erase Resume command can be used to restart the Program/Erase Controller after a Program/Erase Suspend operation has paused it. One Bus Write cycle is required to issue the command. Once the command is issued subsequent Bus Read operations read the Status Register.

See Appendix C, Figure 20, Program Suspend & Resume Flowchart and Pseudo Code, and Figure 22, Erase Suspend & Resume Flowchart and Pseudo Code for flowcharts for using the Program/Erase Resume command.

Protection Register Program Command

The Protection Register Program command is used to Program the 128 bit user One-Time-Programmable (OTP) segment of the Protection Register. The segment is programmed 16 bits at a time. When shipped all bits in the segment are set to '1'. The user can only program the bits to '0'.

Two write cycles are required to issue the Protection Register Program command.

- The first bus cycle sets up the Protection Register Program command.
- The second latches the Address and the Data to be written to the Protection Register and starts the Program/Erase Controller.

Read operations output the Status Register content after the programming has started.

The segment can be protected by programming bit 1 of the Protection Lock Register (see Figure 6, Protection Register Memory Map). Attempting to program a previously protected Protection Register will result in a Status Register error. The protection of the Protection Register is not reversible.

The Protection Register Program cannot be suspended.

Block Lock Command

The Block Lock command is used to lock a block and prevent Program or Erase operations from changing the data in it. All blocks are locked at power-up or reset.

Two Bus Write cycles are required to issue the Block Lock command.

- The first bus cycle sets up the Block Lock command.
- The second Bus Write cycle latches the block address.

The lock status can be monitored for each block using the Read Electronic Signature command. Table. 10 shows the protection status after issuing a Block Lock command.

The Block Lock bits are volatile, once set they remain set until a hardware reset or power-down/power-up. They are cleared by a Blocks Unlock command. Refer to the section, Block Locking, for a detailed explanation.

Block Unlock Command

The Blocks Unlock command is used to unlock a block, allowing the block to be programmed or erased. Two Bus Write cycles are required to issue the Blocks Unlock command.

- The first bus cycle sets up the Block Unlock command.
- The second Bus Write cycle latches the block address.

The lock status can be monitored for each block using the Read Electronic Signature command. Table. 10 shows the protection status after issuing a Block Unlock command. Refer to the section, Block Locking, for a detailed explanation.

Block Lock-Down Command

A locked block cannot be Programmed or Erased, or have its protection status changed when $\overline{WP}$ is low, V_{IL}. When $\overline{WP}$ is high, V_{IH}, the Lock-Down function is disabled and the locked blocks can be individually unlocked by the Block Unlock command.

Two Bus Write cycles are required to issue the Block Lock-Down command.

- The first bus cycle sets up the Block Lock command.
- The second Bus Write cycle latches the block address.

The lock status can be monitored for each block using the Read Electronic Signature command. Locked-Down blocks revert to the locked (and not

locked-down) state when the device is reset on power-down. Table. 10 shows the protection status after issuing a Block Lock-Down command. Refer to the section, Block Locking, for a detailed explanation.

Table 4. Commands

Commands	Cycles	Bus Write Operations														
		1st Cycle			2nd Cycle			3rd Cycle			4th Cycle			5th Cycle		
		Op.	Add	Data	Op.	Add	Data	Op.	Add	Data	Op.	Add	Data	Op.	Add	Data
Read Memory Array	1+	Write	X	FFh	Read	RA	RD									
Read Status Register	1+	Write	X	70h	Read	X	SRD									
Read Electronic Signature	1+	Write	X	90h	Read	SA(2)	IDh									
Read CFI Query	1+	Write	X	98h	Read	QA	QD									
Erase	2	Write	X	20h	Write	BA	D0h									
Program	2	Write	X	40h or 10h	Write	PA	PD									
Double Word Program(3)	3	Write	X	30h	Write	PA1	PD1	Write	PA2	PD2						
Quadruple Word Program(4)	5	Write	X	56h(5)	Write	PA1	PD1	Write	PA2	PD2	Write	PA3	PD3	Write	PA4	PD4
Clear Status Register	1	Write	X	50h												
Program/Erase Suspend	1	Write	X	B0h												
Program/Erase Resume	1	Write	X	D0h												
Block Lock	2	Write	X	60h	Write	BA	01h									
Block Unlock	2	Write	X	60h	Write	BA	D0h									
Block Lock-Down	2	Write	X	60h	Write	BA	2Fh									
Protection Register Program	2	Write	X	C0h	Write	PRA	PRD									

Note: 1. X = Don't Care, RA=Read Address, RD=Read Data, SRD=Status Register Data, ID=Identifier (Manufacture and Device Code), QA=Query Address, QD=Query Data, BA=Block Address, PA=Program Address, PD=Program Data, PRA=Protection Register Address, PRD=Protection Register Data.
2. The signature addresses are listed in Tables 5, 6 and 7.
3. Program Addresses 1 and 2 must be consecutive Addresses differing only for A0.
4. Program Addresses 1,2,3 and 4 must be consecutive Addresses differing only for A0 and A1.
5. To be characterized.

Table 5. Read Electronic Signature

Code	Device	$\overline{E}$	$\overline{G}$	$\overline{W}$	A0	A1	A2-A7	A8-A21	DQ0-DQ7	DQ8-DQ15

Table 8. Program, Erase Times and Program/Erase Endurance Cycles

Parameter	Test Conditions	M28W640EC			Unit
		Min	Typ	Max	
Word Program	$V_{PP} = V_{DD}$		10	200	µs
Double Word Program	V_{PP} = 12V ±5%		10	200	µs
Quadruple Word Program	V_{PP} = 12V ±5%		10	200	µs
Main Block Program	V_{PP} = 12V ±5%		0.16/0.08 (1)	5	s
	$V_{PP} = V_{DD}$		0.32	5	s
Parameter Block Program	V_{PP} = 12V ±5%		0.02/0.01 (1)	4	s
	$V_{PP} = V_{DD}$		0.04	4	s
Main Block Erase	V_{PP} = 12V ±5%		1	10	s
	$V_{PP} = V_{DD}$		1	10	s
Parameter Block Erase	V_{PP} = 12V ±5%		0.4	10	s
	$V_{PP} = V_{DD}$		0.4	10	s
Program/Erase Cycles (per Block)		100,000			cycles

Note: 1. Typical time to program a Main or Parameter Block using the Double Word Program and the Quadruple Word Program commands respectively.

BLOCK LOCKING

The M28W640EC features an instant, individual block locking scheme that allows any block to be locked or unlocked with no latency. This locking scheme has three levels of protection.

- Lock/Unlock - this first level allows software-only control of block locking.
- Lock-Down - this second level requires hardware interaction before locking can be changed.
- $V_{PP} \leq V_{PPLK}$ - the third level offers a complete hardware protection against program and erase on all blocks.

The protection status of each block can be set to Locked, Unlocked, and Lock-Down. Table 10, defines all of the possible protection states ($\overline{WP}$, DQ1, DQ0), and Appendix C, Figure 23, shows a flowchart for the locking operations.

Reading a Block's Lock Status

The lock status of every block can be read in the Read Electronic Signature mode of the device. To enter this mode write 90h to the device. Subsequent reads at the address specified in Table 6, will output the protection status of that block. The lock status is represented by DQ0 and DQ1. DQ0 indicates the Block Lock/Unlock status and is set by the Lock command and cleared by the Unlock command. It is also automatically set when entering Lock-Down. DQ1 indicates the Lock-Down status and is set by the Lock-Down command. It cannot be cleared by software, only by a hardware reset or power-down.

The following sections explain the operation of the locking system.

Locked State

The default status of all blocks on power-up or after a hardware reset is Locked (states (0,0,1) or (1,0,1)). Locked blocks are fully protected from any program or erase. Any program or erase operations attempted on a locked block will return an error in the Status Register. The Status of a Locked block can be changed to Unlocked or Lock-Down using the appropriate software commands. An Unlocked block can be Locked by issuing the Lock command.

Unlocked State

Unlocked blocks (states (0,0,0), (1,0,0) (1,1,0)), can be programmed or erased. All unlocked blocks return to the Locked state after a hardware reset or when the device is powered-down. The status of an unlocked block can be changed to Locked or Locked-Down using the appropriate software commands. A locked block can be unlocked by issuing the Unlock command.

Lock-Down State

Blocks that are Locked-Down (state (0,1,x))are protected from program and erase operations (as for Locked blocks) but their protection status cannot be changed using software commands alone. A Locked or Unlocked block can be Locked-Down by issuing the Lock-Down command. Locked-Down blocks revert to the Locked state when the device is reset or powered-down.

The Lock-Down function is dependent on the $\overline{WP}$ input pin. When $\overline{WP}$=0 (V_{IL}), the blocks in the Lock-Down state (0,1,x) are protected from program, erase and protection status changes. When $\overline{WP}$=1 (V_{IH}) the Lock-Down function is disabled (1,1,1) and Locked-Down blocks can be individually unlocked to the (1,1,0) state by issuing the software command, where they can be erased and programmed. These blocks can then be relocked (1,1,1) and unlocked (1,1,0) as desired while $\overline{WP}$ remains high. When $\overline{WP}$ is low , blocks that were previously Locked-Down return to the Lock-Down state (0,1,x) regardless of any changes made while $\overline{WP}$ was high. Device reset or power-down resets all blocks , including those in Lock-Down, to the Locked state.

Locking Operations During Erase Suspend

Changes to block lock status can be performed during an erase suspend by using the standard locking command sequences to unlock, lock or lock-down a block. This is useful in the case when another block needs to be updated while an erase operation is in progress.

To change block locking during an erase operation, first write the Erase Suspend command, then check the status register until it indicates that the erase operation has been suspended. Next write the desired Lock command sequence to a block and the lock status will be changed. After completing any desired lock, read, or program operations, resume the erase operation with the Erase Resume command.

If a block is locked or locked-down during an erase suspend of the same block, the locking status bits will be changed immediately, but when the erase is resumed, the erase operation will complete.

Locking operations cannot be performed during a program suspend. Refer to Appendix D, Command Interface and Program/Erase Controller State, for detailed information on which commands are valid during erase suspend.

Table 9. Block Lock Status

Item	Address	Data
Block Lock Configuration	xx002	LOCK
Block is Unlocked		DQ0=0
Block is Locked		DQ0=1
Block is Locked-Down		DQ1=1

Table 10. Protection Status

Current Protection Status(1) ($\overline{WP}$, DQ1, DQ0)		Next Protection Status(1) ($\overline{WP}$, DQ1, DQ0)			
Current State	**Program/Erase Allowed**	**After Block Lock Command**	**After Block Unlock Command**	**After Block Lock-Down Command**	**After $\overline{WP}$ transition**
1,0,0	yes	1,0,1	1,0,0	1,1,1	0,0,0
1,0,1(2)	no	1,0,1	1,0,0	1,1,1	0,0,1
1,1,0	yes	1,1,1	1,1,0	1,1,1	0,1,1
1,1,1	no	1,1,1	1,1,0	1,1,1	0,1,1
0,0,0	yes	0,0,1	0,0,0	0,1,1	1,0,0
0,0,1(2)	no	0,0,1	0,0,0	0,1,1	1,0,1
0,1,1	no	0,1,1	0,1,1	0,1,1	1,1,1 or 1,1,0 (3)

Note: 1. The lock status is defined by the write protect pin and by DQ1 ('1' for a locked-down block) and DQ0 ('1' for a locked block) as read in the Read Electronic Signature command with A1 = V_{IH} and A0 = V_{IL}.
2. All blocks are locked at power-up, so the default configuration is 001 or 101 according to $\overline{WP}$ status.
3. A $\overline{WP}$ transition to V_{IH} on a locked block will restore the previous DQ0 value, giving a 111 or 110.

STATUS REGISTER

The Status Register provides information on the current or previous Program or Erase operation. The various bits convey information and errors on the operation. To read the Status register the Read Status Register command can be issued, refer to Read Status Register Command section. To output the contents, the Status Register is latched on the falling edge of the Chip Enable or Output Enable signals, and can be read until Chip Enable or Output Enable returns to V_{IH}. Either Chip Enable or Output Enable must be toggled to update the latched data.

Bus Read operations from any address always read the Status Register during Program and Erase operations.

The bits in the Status Register are summarized in Table 11, Status Register Bits. Refer to Table 11 in conjunction with the following text descriptions.

Program/Erase Controller Status (Bit 7). The Program/Erase Controller Status bit indicates whether the Program/Erase Controller is active or inactive. When the Program/Erase Controller Status bit is Low (set to '0'), the Program/Erase Controller is active; when the bit is High (set to '1'), the Program/Erase Controller is inactive, and the device is ready to process a new command.

The Program/Erase Controller Status is Low immediately after a Program/Erase Suspend command is issued until the Program/Erase Controller pauses. After the Program/Erase Controller pauses the bit is High .

During Program, Erase, operations the Program/Erase Controller Status bit can be polled to find the end of the operation. Other bits in the Status Register should not be tested until the Program/Erase Controller completes the operation and the bit is High.

After the Program/Erase Controller completes its operation the Erase Status, Program Status, V_{PP} Status and Block Lock Status bits should be tested for errors.

Erase Suspend Status (Bit 6). The Erase Suspend Status bit indicates that an Erase operation has been suspended or is going to be suspended. When the Erase Suspend Status bit is High (set to '1'), a Program/Erase Suspend command has been issued and the memory is waiting for a Program/Erase Resume command.

The Erase Suspend Status should only be considered valid when the Program/Erase Controller Status bit is High (Program/Erase Controller inactive). Bit 7 is set within 30µs of the Program/Erase Suspend command being issued therefore the memory may still complete the operation rather than entering the Suspend mode.

When a Program/Erase Resume command is issued the Erase Suspend Status bit returns Low.

Erase Status (Bit 5). The Erase Status bit can be used to identify if the memory has failed to verify that the block has erased correctly. When the Erase Status bit is High (set to '1'), the Program/Erase Controller has applied the maximum number of pulses to the block and still failed to verify that the block has erased correctly. The Erase Status bit should be read once the Program/Erase Controller Status bit is High (Program/Erase Controller inactive).

Once set High, the Erase Status bit can only be reset Low by a Clear Status Register command or a hardware reset. If set High it should be reset before a new Program or Erase command is issued, otherwise the new command will appear to fail.

Program Status (Bit 4). The Program Status bit is used to identify a Program failure. When the Program Status bit is High (set to '1'), the Program/Erase Controller has applied the maximum number of pulses to the byte and still failed to verify that it has programmed correctly. The Program Status bit should be read once the Program/Erase Controller Status bit is High (Program/Erase Controller inactive).

Once set High, the Program Status bit can only be reset Low by a Clear Status Register command or a hardware reset. If set High it should be reset before a new command is issued, otherwise the new command will appear to fail.

V_{PP} Status (Bit 3). The V_{PP} Status bit can be used to identify an invalid voltage on the V_{PP} pin during Program and Erase operations. The V_{PP} pin is only sampled at the beginning of a Program or Erase operation. Indeterminate results can occur if V_{PP} becomes invalid during an operation.

When the V_{PP} Status bit is Low (set to '0'), the voltage on the V_{PP} pin was sampled at a valid voltage; when the V_{PP} Status bit is High (set to '1'), the V_{PP} pin has a voltage that is below the V_{PP} Lockout Voltage, V_{PPLK}, the memory is protected and Program and Erase operations cannot be performed.

Once set High, the V_{PP} Status bit can only be reset Low by a Clear Status Register command or a hardware reset. If set High it should be reset before a new Program or Erase command is issued, otherwise the new command will appear to fail.

Program Suspend Status (Bit 2). The Program Suspend Status bit indicates that a Program operation has been suspended. When the Program Suspend Status bit is High (set to '1'), a Program/Erase Suspend command has been issued and the memory is waiting for a Program/Erase Resume command. The Program Suspend Status should only be considered valid when the Pro-

gram/Erase Controller Status bit is High (Program/ Erase Controller inactive). Bit 2 is set within 5µs of the Program/Erase Suspend command being issued therefore the memory may still complete the operation rather than entering the Suspend mode.

When a Program/Erase Resume command is issued the Program Suspend Status bit returns Low.

Block Protection Status (Bit 1). The Block Protection Status bit can be used to identify if a Program or Erase operation has tried to modify the contents of a locked block.

When the Block Protection Status bit is High (set to '1'), a Program or Erase operation has been attempted on a locked block.

Once set High, the Block Protection Status bit can only be reset Low by a Clear Status Register command or a hardware reset. If set High it should be reset before a new command is issued, otherwise the new command will appear to fail.

Reserved (Bit 0). Bit 0 of the Status Register is reserved. Its value must be masked.

Note: Refer to Appendix C, Flowcharts and Pseudo Codes, for using the Status Register.

Table 11. Status Register Bits

Bit	Name	Logic Level	Definition
7	P/E.C. Status	'1'	Ready
		'0'	Busy
6	Erase Suspend Status	'1'	Suspended
		'0'	In progress or Completed
5	Erase Status	'1'	Erase Error
		'0'	Erase Success
4	Program Status	'1'	Program Error
		'0'	Program Success
3	V_{PP} Status	'1'	V_{PP} Invalid, Abort
		'0'	V_{PP} OK
2	Program Suspend Status	'1'	Suspended
		'0'	In Progress or Completed
1	Block Protection Status	'1'	Program/Erase on protected Block, Abort
		'0'	No operation to protected blocks
0	Reserved		

Note: Logic level '1' is High, '0' is Low.

MAXIMUM RATING

Stressing the device above the rating listed in the Absolute Maximum Ratings table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

Table 12. Absolute Maximum Ratings

Symbol	Parameter	Value		Unit
		Min	Max	
T_A	Ambient Operating Temperature (1)	– 40	85	°C
T_{BIAS}	Temperature Under Bias	– 40	125	°C
T_{STG}	Storage Temperature	– 55	155	°C
V_{IO}	Input or Output Voltage	– 0.6	V_{DDQ}+0.6	V
V_{DD}, V_{DDQ}	Supply Voltage	– 0.6	4.1	V
V_{PP}	Program Voltage	– 0.6	13	V

Note: 1. Depends on range.

DC AND AC PARAMETERS

This section summarizes the operating and measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC characteristics Tables that follow, are derived from tests performed under the Measurement Conditions summarized in Table 13, Operating and AC Measurement Conditions. Designers should check that the operating conditions in their circuit match the measurement conditions when relying on the quoted parameters.

Table 13. Operating and AC Measurement Conditions

Parameter	M28W640ECT, M28W640ECB								Units
	70[1]		85		90		10		
	Min	Max	Min	Max	Min	Max	Min	Max	
V_{DD} Supply Voltage	3.0	3.6	3.0	3.6	2.7	3.6	2.7	3.6	V
V_{DDQ} Supply Voltage ($V_{DDQ} \leq V_{DD}$)	1.65	3.6	1.65	3.6	1.65	3.6	1.65	3.6	V
Ambient Operating Temperature	– 40	85	– 40	85	– 40	85	– 40	85	°C
Load Capacitance (C_L)	50		50		50		50		pF
Input Rise and Fall Times		5		5		5		5	ns
Input Pulse Voltages	0 to V_{DDQ}		0 to V_{DDQ}		0 to V_{DDQ}		0 to V_{DDQ}		V
Input and Output Timing Ref. Voltages	$V_{DDQ}/2$		$V_{DDQ}/2$		$V_{DDQ}/2$		$V_{DDQ}/2$		V

Note: 1. To be characterized.
