

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Remote Temperature Sensor with SMBus Serial Interface

MAX1618†

General Description

The MAX1618 precise digital thermometer reports the temperature of a remote sensor. The remote sensor is a diode-connected transistor—typically a low-cost, easily mounted 2N3904 NPN type—that replaces conventional thermistors or thermocouples. Remote accuracy is $\pm 3^{\circ}\text{C}$ for multiple transistor manufacturers, with no calibration needed. The MAX1618 can also measure the die temperature of other ICs, such as microprocessors, that contain an on-chip, diode-connected transistor.

The 2-wire serial interface accepts standard System Management Bus (SMBus™) Write Byte, Read Byte, Send Byte, and Receive Byte commands to program the alarm thresholds and to read temperature data. The data format is 7 bits plus sign, with each bit corresponding to 1°C , in two's complement format. Measurements can be done automatically and autonomously, with the 16Hz conversion rate or programmed to operate in a single-shot mode.

The thermostat mode configures the $\overline{\text{ALERT}}$ output as an interrupt or as a temperature reset that remains active only while the temperature is above the maximum temperature limit or below the minimum temperature limit. The $\overline{\text{ALERT}}$ output polarity in thermostat mode can be configured for active high or active low. Fan control is implemented using this $\overline{\text{ALERT}}$ output.

The MAX1618 is available in a small (1.1mm high) 10-pin μMAX package.

Applications

Desktop and Notebook Computers	Central Office Telecom Equipment
Smart Battery Packs	Test and Measurement
LAN Servers	Multichip Modules
Industrial Controls	

Pin Configuration

SMBus is a trademark of Intel Corp.
† Patents Pending

Features

- ◆ **Single Channel: Measures Remote CPU Temperature**
- ◆ **No Calibration Required**
- ◆ **SMBus 2-Wire Serial Interface**
- ◆ **Programmable Under/Overtemperature Alarms**
- ◆ **Overtemperature Output for Fan Control (Thermostat Mode)**
- ◆ **Supports SMBus Alert Response Accuracy**
 $\pm 3^{\circ}\text{C}$ ($+60^{\circ}\text{C}$ to $+100^{\circ}\text{C}$)
 $\pm 5^{\circ}\text{C}$ (-55°C to $+120^{\circ}\text{C}$)
- ◆ **3 μA (typ) Standby Supply Current**
- ◆ **900 μA (max) Supply Current in Autoconvert Mode**
- ◆ **+3V to +5.5V Supply Range**
- ◆ **Small 10-Pin μMAX Package**

Remote Temperature Sensor with SMBus Serial Interface

ABSOLUTE MAXIMUM RATINGS

V _{CC} to GND	-0.3V to +6V	Continuous Power Dissipation (T _A = +70°C)
DXP, ADD ₋ to GND	-0.3V to (V _{CC} + 0.3V)	μMAX (derate 5.6mW/°C above +70°C)
DXN to GND	-0.3V to +0.8V	444mW
SMBCLK, SMBDATA, ALERT, STBY to GND	-0.3V to +6V	Operating Temperature Range (extended)
SMBDATA Current.....	-1mA to 50mA	-55°C to +125°C
DXN Current	±1mA	Junction Temperature.....
ESD Protection (all pins, Human Body Model).....	± 2000V	+150°C
		Storage Temperature Range
		-65°C to +150°C
		Lead Temperature (soldering, 10s)
		+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V_{CC} = +3.3V, configuration byte register = X8h, T_A = 0°C to +85°C, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS	
ADC AND POWER SUPPLY

ELECTRICAL CHARACTERISTICS (continued)

(V_{CC} = +3.3V, configuration byte register = X8h, T_A = -55°C to +125°C, unless otherwise noted.) (Note 5)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
SMBus INTERFACE					
STBY, SMBCLK, SMBDATA Input High Voltage	V _{CC} = 3.0V	2.2			V
	V _{CC} = 5.5V	2.4			
STBY, SMBCLK, SMBDATA Input Low Voltage	V _{CC} = 3.0V to 5.5V			0.8	V
STBY, SMBCLK, SMBDATA Input Current	Logic inputs forced to V _{CC} or GND	-2		2	μA
SMBCLK, SMBDATA Output Low Sink Current	SMBCLK, SMBDATA forced to 0.6V	6			mA
ALERT Output Low Sink Current	ALERT forced to 0.4V	1			mA
ALERT Output High Leakage Current	ALERT forced to 5.5V			1	μA

Note 1: Guaranteed, but not 100% tested.

Note 2: A remote diode is any diode-connected transistor from Table 7. T_R is the junction temperature of the remote diode. See *Remote Diode Selection* for remote-diode forward voltage requirements. Temperature specification guaranteed for a diode with ideality factor (M_{TR} = 1.013). Additional error = (1.013/M - 1) × 273 + Temp where M = Ideality of remote diode used.

Note 3: The SMBus logic block is a static design that works with clock frequencies down to DC. While slow operation is possible, it violates the 10kHz minimum clock frequency and SMBus specifications and may monopolize the bus.

Note 4: Note that a transition must internally provide at least a hold time to bridge the undefined region (300ns max) of SMBCLK's falling edge.

Note 5: Specifications from -55°C to +125°C are guaranteed by design, not production tested.

Remote Temperature Sensor with SMBus Serial Interface

Pin Description

PIN	NAME	FUNCTION
1	ADD0	SMBus Slave Address Select Input. (See Table 6.) ADD0 and ADD1 are sampled upon power-up. Excess capacitance (>50pF) at the address pins when floating may cause address-recognition problems.
2	ADD1	SMBus Slave Address Select Input. (See Table 6.) ADD0 and ADD1 are sampled upon power-up. Excess capacitance (>50pF) at the address pins when floating may cause address-recognition problems.
3	GND	Ground
4	DXN	Combined Current Sink and A/D Negative Input. DXN is normally biased to a diode voltage above ground.
5	DXP	Combined Current Source and A/D Positive Input. Do not leave DXP floating. Place a 2200pF capacitor between DXP and DXN for noise filtering.
6	V _{CC}	Supply Voltage Input. Bypass to GND with a 0.1μF capacitor.
7	$\overline{\text{STBY}}$	Hardware-Standby Input. Temperature and comparison threshold data are retained in standby mode. Low = standby mode. High = operating mode.
8	SMBCLK	SMBus Serial-Clock Input
9	SMBDATA	SMBus Serial-Data Input/Output. Open drain.
10	$\overline{\text{ALERT}}$	SMBus Alert (Interrupt) Output. Open drain.

Detailed Description

The MAX1618 is a temperature sensor designed to work in conjunction with an external microcontroller (μC) or other intelligence in thermostatic, process-control, or monitoring applications. The μC is typically a power-management or keyboard controller, generating SMBus serial commands by “bit-banging” general-purpose input-output (GPIO) pins or through a dedicated SMBus interface block.

Essentially an 8-bit serial analog-to-digital converter (ADC) with a sophisticated front end, the MAX1618 contains a switched-current source, a multiplexer, an ADC, an SMBus interface, and the associated control logic (Figure 1). Temperature data from the ADC is loaded into a data register, where it is automatically compared with data previously stored in over/under-temperature alarm threshold registers. The alarm threshold registers can be set for hysteretic fan control.

ADC and Multiplexer

The averaging ADC integrates over a 30ms period (typ) with excellent noise rejection. The ADC converts at a rate of 16Hz. The multiplexer automatically steers bias

currents through the remote diode, measures the forward voltage, and computes the temperature.

The DXN input is biased at 0.65V above ground by an internal diode to set up the analog-to-digital (A/D) inputs for a differential measurement. The worst-case DXP-DXN differential input voltage range is 0.25V to 0.95V.

Excess resistance in series with the remote diode causes about $+1/2^\circ\text{C error}/\Omega$. A 200 μV offset voltage at DXP-DXN causes about $+1^\circ\text{C error}$.

A/D Conversion Sequence

If a Start command is written (or generated automatically in the free-running autoconvert mode), the result of the measurement is available after the end of conversion. A BUSY status bit in the status byte shows that the device is performing a new conversion. The result of the previous conversion is always available even when the ADC is busy.

Remote Temperature Sensor with SMBus Serial Interface

MAX1618

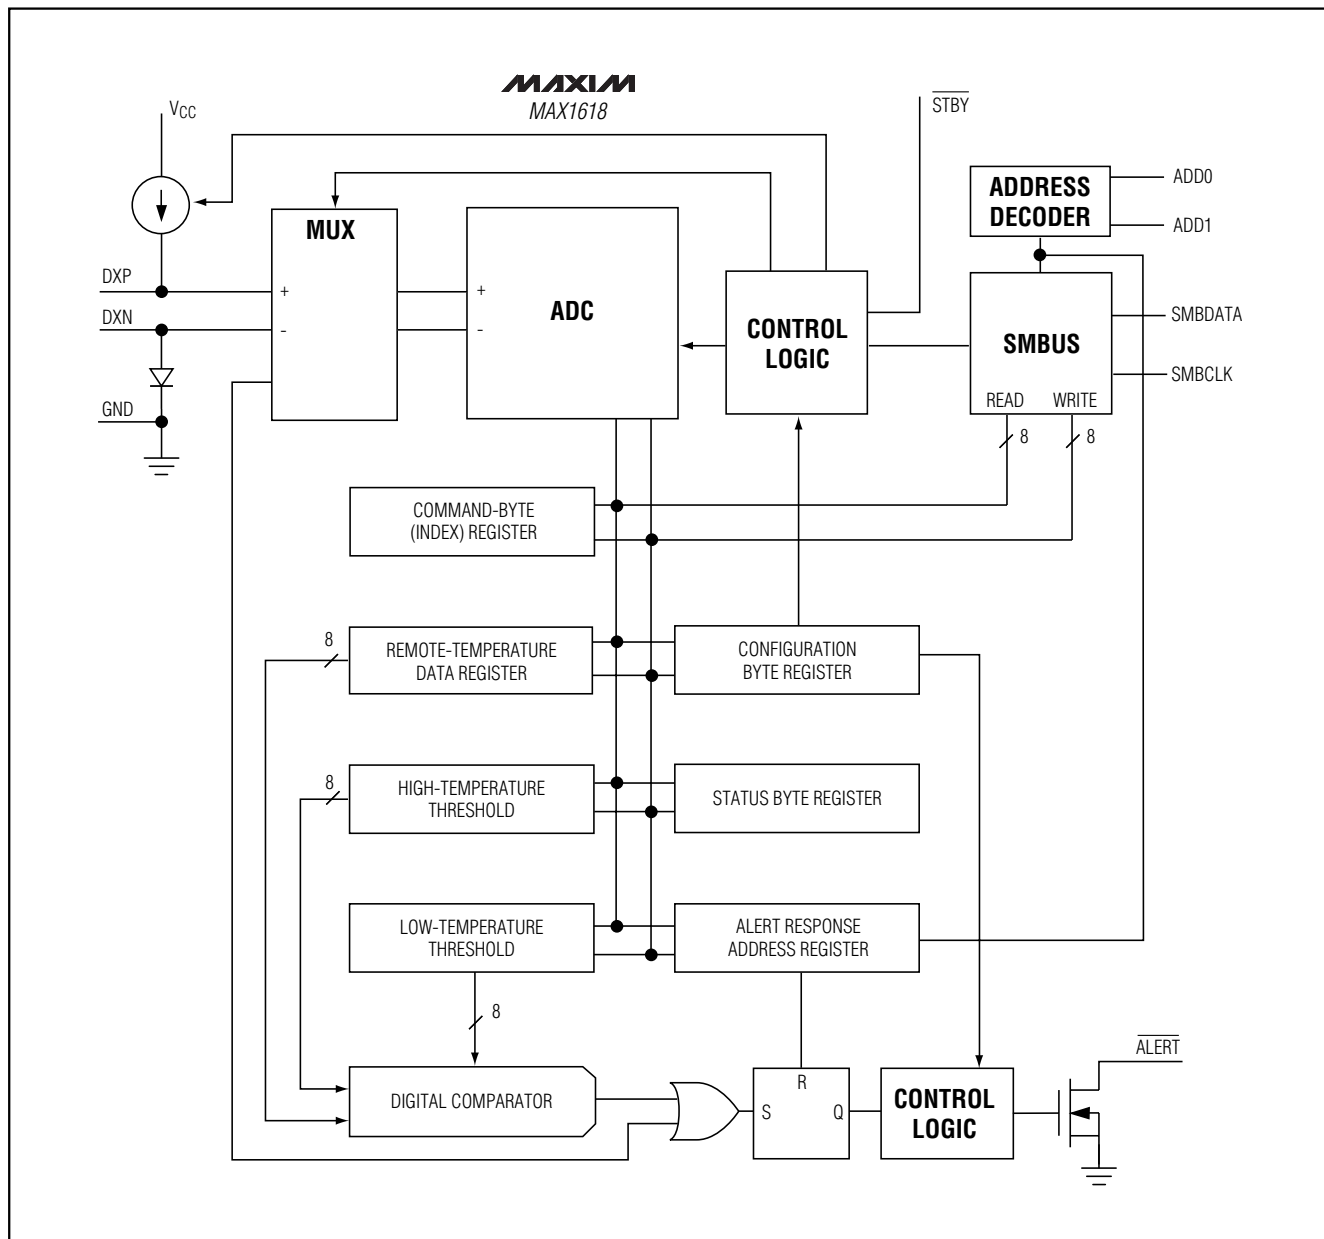

Figure 1. Functional Diagram

Remote Temperature Sensor with SMBus Serial Interface

Low-Power Standby Mode

Standby mode disables the ADC and reduces the supply-current drain to 3 μ A (typ). Enter standby mode by forcing the $\overline{\text{STBY}}$ pin low or through the RUN/STOP bit in the configuration-byte register. Hardware and software standby modes behave almost identically; all data is retained in memory, and the SMB interface is alive and listening for reads and writes. The only difference is that in hardware-standby mode, the one-shot command does not initiate a conversion.

Standby mode is not a shutdown mode. Activity on the SMBus draws extra supply current (see *Typical Operating Characteristics*). In software-standby mode, the MAX1618 can be forced to perform A/D conversions through the one-shot command, despite the RUN/STOP bit being high.

Enter hardware standby mode by forcing the $\overline{\text{STBY}}$ pin low. In a notebook computer, this line may be connected to the system SUSTAT# suspend-state signal.

The $\overline{\text{STBY}}$ pin low state overrides any software conversion command. If a hardware- or software-standby command is received while a conversion is in progress, the conversion cycle is truncated, and the data from that conversion is not latched into either temperature-reading register. The previous data is not changed and remains available.

Supply-current drain during the 62ms conversion period is always about 450 μ A. Between conversions, the instantaneous supply current is about 25 μ A due to the current consumed by the conversion-rate timer. In standby mode, supply current drops to about 3 μ A. With very low supply voltages (under the power-on reset threshold), the supply current is higher due to the address input bias currents. It can be as high as 160 μ A, depending on ADD0 and ADD1 settings.

SMBus Digital Interface

From a software perspective, the MAX1618 appears as a set of byte-wide registers that contains temperature data, alarm threshold values, or control bits. Use a standard SMBus 2-wire serial interface to read temperature data and write control bits and alarm threshold data.

The MAX1618 employs four standard SMBus protocols: Write Byte, Read Byte, Send Byte, and Receive Byte (Figure 2). The two shorter protocols (Receive and Send) allow quicker transfers, provided that the correct data register was previously selected by a Write or Read Byte instruction. Use caution with the shorter protocols in multimaster systems, since a second master could overwrite the command byte without informing the first master.

Table 1. Data Format (Two's Complement)

TEMP. (°C)	ROUNDED TEMP. (°C)	DIGITAL OUTPUT DATA BITS		
		SIGN	MSB	LSB
+130.00	+127	0	111	1111
+127.00	+127	0	111	1111
+126.50	+127	0	111	1111
+126.00	+126	0	111	1111
+25.25	+25	0	001	1001
+0.50	+1	0	000	0001
+0.25	0	0	000	0000
0.00	0	0	000	0000
-0.25	0	0	000	0000
-0.50	0	0	000	0000
-0.75	-1	1	111	1111
-1.00	-1	1	111	1111
-25.00	-25	1	110	0111
-25.50	-25	1	110	0111
-54.75	-55	1	100	1001
-55.00	-55	1	100	1001
-65.00	-65	1	011	1111
-70.00	-65	1	011	1111

The temperature data format is 7 bits plus sign in two's complement form for each channel, with each data bit representing +1°C (Table 1), transmitted MSB first. Measurements are offset by +1/2°C to minimize internal rounding errors; for example, +99.6°C is reported as +100°C.

Alarm Threshold Registers

Two registers, a high-temperature (T_{HIGH}) and a low-temperature (T_{LOW}) register, store alarm threshold data. If a measured temperature equals or exceeds the corresponding alarm threshold value, an $\overline{\text{ALERT}}$ interrupt is asserted.

The power-on reset (POR) state of the T_{HIGH} register is full scale (0111 1111 or +127°C). The POR state of the T_{LOW} register is 1100 1001 or -55°C.

Thermostat Mode

Thermostat mode changes the function of the $\overline{\text{ALERT}}$ output from a latched interrupt-type output to a self-clearing thermostat for fan control. This output simply responds to the current temperature (Figure 3). If the current temperature is above T_{HIGH} , $\overline{\text{ALERT}}$ activates

Remote Temperature Sensor with SMBus Serial Interface

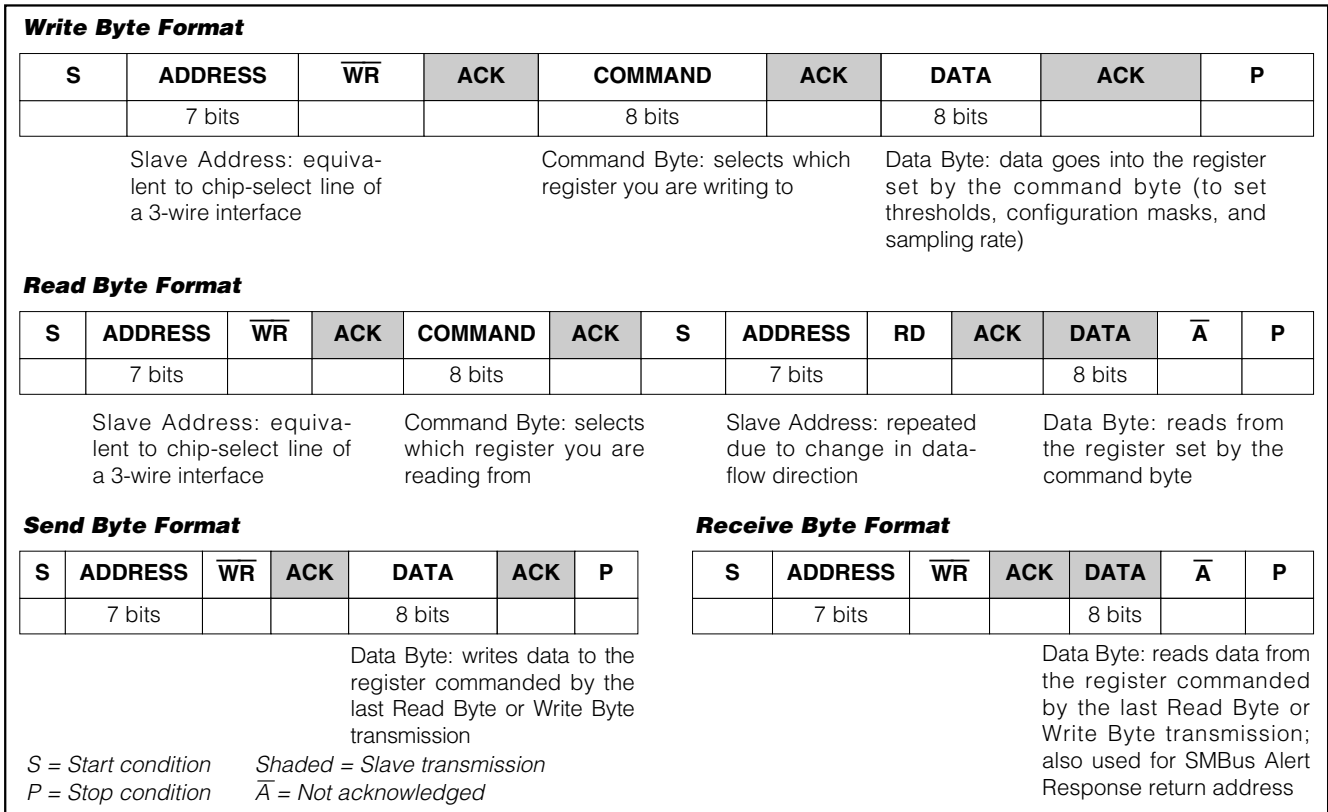

Figure 2. SMBus Protocols

Figure 3. Fan Control Application

and does not go inactive until the temperature drops below T_{LOW} .

Enable thermostat mode through the configuration register (Table 4), with one bit to enable the feature and another bit to set the output polarity (active high or active low). The \overline{ALERT} thermostat comparison is made after each conversion, or at the end of any SMBus transaction. For example, if the limit is changed while the device is in standby mode, the \overline{ALERT} output responds correctly according to the last valid A/D result. Upon entering thermostat mode, the \overline{ALERT} output is reset so that if the temperature is in the hysteresis band \overline{ALERT} initially goes inactive. The power-on reset (POR) state disables thermostat mode.

Diode Fault Alarm

A continuity fault detector at DXP detects whether the remote diode has an open-circuit condition, short-circuit to GND, or short-circuit DXP-to-DXN condition. At the beginning of each conversion, the diode fault is checked, and the status byte is updated. This fault detector is a simple voltage detector; if DXP rises

Remote Temperature Sensor with SMBus Serial Interface

above $V_{CC} - 1V$ (typ) or below $V_{DXN} + 50mV$ (typ), a fault is detected and \overline{ALERT} is asserted. ADC reads $+127^{\circ}C$. Also, if the ADC has an extremely low differential input voltage, the diode is assumed to be shorted and a fault is detected. Note that the diode fault is not checked until a conversion is initiated, so immediately after power-on reset, the status byte indicates no fault is present even if the diode path is broken.

\overline{ALERT} Interrupts

Normally, the \overline{ALERT} interrupt output signal is latched and can be cleared only by reading the Alert Response address. Interrupts are generated in response to T_{HIGH} and T_{LOW} comparisons and when the remote diode is faulted. The interrupt does not halt automatic conversions; new temperature data continues to be available over the SMBus interface after \overline{ALERT} is asserted. The interrupt output pin is open-drain so the devices can share a common interrupt line.

The interface responds to the SMBus Alert Response address, an interrupt pointer return-address feature (see *Alert Response Address* section). Before taking corrective action, always check to ensure that an interrupt is valid by reading the current temperature.

The alert activates only once per crossing of a given temperature threshold to prevent any re-entrant interrupts. To enable a new interrupt, rewrite the value of the violated temperature threshold.

Alert Response Address

The SMBus Alert Response interrupt pointer provides quick fault identification for simple slave devices that lack the complex, expensive logic needed to be a bus master. Upon receiving an \overline{ALERT} interrupt signal, the host master can broadcast a Receive Byte transmission to the Alert Response slave address (0001100). Any slave device that generated an interrupt then attempts to identify itself by putting its own address on the bus (Table 2).

The Alert Response can activate several different slave devices simultaneously, similar to the I²C General Call. If more than one slave attempts to respond, bus arbitration rules apply, and the device with the lower address code wins. The losing device does not generate an acknowledgement and continues to hold the \overline{ALERT} line low until serviced (implies that the host interrupt input is level sensitive). Successful reading of the alert response address clears the interrupt latch.

Command Byte Functions

The 8-bit command byte register (Table 3) is the master index that points to the other registers within the MAX1618. The register's POR state is 0000 0001, so a

I²C is a trademark of Philips Corp.

Table 2. Read Format for Alert Response Address (0001 100)

BIT	NAME	FUNCTION
7 (MSB)	ADD7	Provide the current MAX1618 slave address that was latched at POR (Table 6)
6	ADD6	
5	ADD5	
4	ADD4	
3	ADD3	
2	ADD2	
1	ADD1	
0 (LSB)	ADD0	Logic 1

Receive Byte transmission (a protocol that lacks the command byte) that occurs immediately after POR returns the current remote temperature data.

The one-shot command immediately forces a new conversion cycle to begin. A new conversion begins in software standby mode (RUN/STOP bit = high). The device returns to standby mode after the conversion. If a conversion is in progress when a one-shot command is received, the command is ignored. If a one-shot command is received in autoconvert mode (RUN/STOP bit = low) between conversions, a new conversion begins; the conversion rate timer is reset, and the next automatic conversion takes place after a full delay elapses.

Configuration Byte Functions

The configuration byte register (Table 4) is used to mask (disable) interrupts, to put the device in software-standby or thermostat mode, change the polarity of the alert output (thermostat mode only), and to change the diode bias current. The lower three bits are internally driven low (000), making them "don't care" bits. Write zeros to these bits. The serial interface can read back this register's contents.

Status Byte Functions

The status byte register (Table 5) indicates which (if any) temperature thresholds have been exceeded. This byte also indicates whether the ADC is converting and whether there is a fault in the remote diode DXP-DXN path. After POR, the normal state of all the flag bits is zero, assuming none of the alarm conditions is present. The status byte is cleared by any successful read of the status byte. Note that the \overline{ALERT} interrupt latch is not automatically cleared when the status flag bit is cleared.

Remote Temperature Sensor with SMBus Serial Interface

MAX1618

Table 3. Command-Byte Bit Assignments

REGISTER	COMMAND	POR STATE	FUNCTION
RFU	00h	N/A	Reserved for future use
RRTE	01h	0000 0000*	Read remote temperature; returns latest temperature
RSL	02h	N/A	Read status byte (flags, busy signal)
RCL	03h	0000 1000	Read configuration byte
RCRA	04h	0000 0111	Read conversion rate byte (not supported by MAX1618)
RFU	05h	N/A	Reserved for future use
RFU	06h	N/A	Reserved for future use
RRHI	07h	0111 1111	Read remote T _{HIGH} limit
RRLS	08h	1100 1001	Read remote T _{LOW} limit
WCA	09h	N/A	Write configuration byte
WCRW	0Ah	N/A	Write conversion rate byte (not supported by MAX1618)
RFU	0Bh	N/A	Reserved for future use
RFU	0Ch	N/A	Reserved for future use
WRHA	0Dh	N/A	Write remote T _{HIGH} limit
WRLN	0Eh	N/A	Write remote T _{LOW} limit
OSHT	0Fh	N/A	One-shot command
MFGID	FEh	01001101	Read manufacturer ID code
DEVID	FFh	00000010	Read device ID code

*If the device is in hardware-standby mode at POR, the temperature register reads 0°C.

Table 4. Configuration-Byte Bit Assignments

BIT	NAME	POR STATE	FUNCTION
7 (MSB)	MASK	0	Masks all $\overline{\text{ALERT}}$ interrupts when high.
6	RUN/STOP	0	Standby mode control bit. If high, the device immediately stops converting and enters standby mode. If low, the device converts in either one-shot or timer mode.
5	POL	0	$\overline{\text{ALERT}}$ pin polarity control in thermostat mode. 0 = active low 1 = active high
4	THERM	0	Enables thermostat mode when high.
3	ID	1	Enables diode bias current. 0 (Logic Low) = 5 μ A to 50 μ A (typ) 1 (Logic High) = 10 μ A to 100 μ A (typ)
2 to 0	RFU	0	Reserved for future use.

Table 5. Status-Byte Bit Assignments

BIT	NAME	FUNCTION
7 (MSB)	BUSY	A high indicates that the ADC is busy converting.
6, 5	RFU	Reserved for future use (returns 0).
4	RHIGH*	A high indicates that the remote high-temperature alarm has activated. In thermostat mode, this bit is always in the same state as the $\overline{\text{ALERT}}$ output.
3	RLOW*	A high indicates that the remote low-temperature alarm has activated. In thermostat mode, this bit is always zero.
2	DIODE	A high indicates a remote-diode fault (open-circuit, shorted diode, or DXP short to GND).
1, 0 (LSB)	RFU	Reserved for future use (returns 0).

*In $\overline{\text{ALERT}}$ mode, the HIGH and LOW temperature alarm flags stay high until cleared by POR or until the status byte register is read.

Remote Temperature Sensor with SMBus Serial Interface

Table 6. Slave Address Decoding (ADD0 and ADD1)

ADD0	ADD1	ADDRESS
GND	GND	0011 000
GND	High-Z	0011 001
GND	V _{CC}	0011 010
High-Z	GND	0101 001
High-Z	High-Z	0101 010
High-Z	V _{CC}	0101 011
V _{CC}	GND	1001 100
V _{CC}	High-Z	1001 101
V _{CC}	V _{CC}	1001 110

Note: High-Z means the pin is left unconnected and floating.

Slave Addresses

The device address can be set to one of nine different values by pin-strapping ADD0 and ADD1 so more than one MAX1618 can reside on the same bus without address conflicts (Table 6).

The address pin states are checked at POR only, and the address data stays latched to reduce quiescent supply current due to the bias current needed for high-impedance (high-Z) state detection.

The MAX1618 also responds to the SMBus Alert Response slave address (see the *Alert Response Address* section).

POR and UVLO

The MAX1618 has a volatile memory. To prevent ambiguous power-supply conditions from corrupting the data in the memory and causing erratic behavior, a POR voltage detector monitors V_{CC} and clears the memory if V_{CC} falls below 1.7V (typical, see the *Electrical Characteristics* table). When power is first applied and V_{CC} rises above 1.75V (typ), the logic blocks begin operating, although reads and writes at V_{CC} levels below 3V are not recommended. A second V_{CC} comparator, the ADC UVLO comparator, prevents the ADC from converting until there is sufficient headroom (V_{CC} = 2.8V typ).

Power-Up Defaults:

- Interrupt latch is cleared.
- Address select pins are sampled.
- Command byte is set to 01h to facilitate quick remote Receive Byte queries.
- T_{HIGH} and T_{LOW} registers are set to max and min limits, respectively.
- Device is in normal mode. $\overline{\text{ALERT}}$ acts as a latched interrupt output.)

Pentium II is a registered trademark of Intel Corp.

Table 7. SOT23 Type Remote-Sensor Transistor Manufacturers

MANUFACTURER	MODEL NUMBER
Central Semiconductor (USA)	CMPT3904
Fairchild Semiconductor (USA)	MMBT3904
Motorola (USA)	MMBT3904
Rohm Semiconductor (Japan)	SST3904
Siemens (Germany)	SMBT3904
Zetex (England)	FMMT3904CT-ND

Note: Transistors must be diode-connected (short the base to the collector).

Applications Information

Remote Diode Selection

Temperature accuracy depends on having a good-quality, diode-connected, small-signal transistor. Accuracy has been experimentally verified for all of the devices listed in Table 7. The MAX1618 can also directly measure the die temperature of CPUs and other integrated circuits with on-board temperature sensing diodes, such as the Intel Pentium II®.

The transistor must be a small-signal type with a relatively high forward voltage. This ensures that the input voltage is within the A/D input voltage range. The forward voltage must be greater than 0.25V at 10μA at the highest expected temperature. The forward voltage must be less than 0.95V at 100μA at the lowest expected temperature. The base resistance has to be less than 100Ω. Tight specification of forward-current gain (+50 to +150, for example) indicates that the manufacturer has good process controls and that the devices have consistent V_{BE} characteristics. Do not use power transistors.

ADC Noise Filtering

The integrating ADC has inherently good noise rejection, especially of low-frequency signals such as 60Hz/120Hz power-supply hum. Micropower operation places constraints on high-frequency noise rejection. Lay out the PCB carefully with proper external noise filtering for high-accuracy remote measurements in electrically noisy environments.

Filter high-frequency electromagnetic interference (EMI) at DXP and DXN with an external 2200pF capacitor connected between the two inputs. This capacitor can be increased to about 3300pF (max), including cable capacitance. A capacitance higher than 3300pF

Remote Temperature Sensor with SMBus Serial Interface

MAX1618

Figure 4. SMBus Write Timing Diagram

Figure 5. SMBus Read Timing Diagram

introduces errors due to the rise time of the switched-current source.

PC Board Layout

- 1) Place the MAX1618 as close as practical to the remote diode. In a noisy environment, such as a computer motherboard, this distance can be 4 inches to 8 inches (typ) or more, as long as the worst noise sources (such as CRTs, clock generators, memory buses, and ISA/PCI buses) are avoided.
- 2) Do not route the DXP–DXN lines next to the deflection coils of a CRT. Also, do not route the traces across a fast memory bus, which can easily introduce +30°C error, even with good filtering. Otherwise, most noise sources are fairly benign.

- 3) Route the DXP and DXN traces parallel and close to each other, away from any high-voltage traces such as +12V_{DC}. Avoid leakage currents from PC board contamination. A 20MΩ leakage path from DXP to ground causes approximately +1°C error.
- 4) Connect guard traces to GND on either side of the DXP–DXN traces (Figure 5). With guard traces in place, routing near high-voltage traces is no longer an issue.
- 5) Route as few vias and crossunders as possible to minimize copper/solder thermocouple effects.

Remote Temperature Sensor with SMBus Serial Interface

Figure 6. Recommended DXP/DXN PC Traces

- 6) When introducing a thermocouple, make sure that both the DXP and the DXN paths have matching thermocouples. In general, PC board-induced thermocouples are not a serious problem. A copper-solder thermocouple exhibits $3\mu\text{V}/^\circ\text{C}$, and it takes approximately $200\mu\text{V}$ of voltage error at DXP-DXN to cause a $+1^\circ\text{C}$ measurement error, so most parasitic thermocouple errors are swamped out.
- 7) Use wide traces. Narrow traces are more inductive and tend to pick up radiated noise. The 10mil widths and spacings recommended in Figure 5 are not absolutely necessary (as they offer only a minor improvement in leakage and noise), but try to use them where practical.
- 8) Note that copper cannot be used as an EMI shield. Use only ferrous materials such as steel. Placing a copper ground plane between the DXP-DXN traces and traces carrying high-frequency noise signals does not help reduce EMI.

Twisted Pair and Shielded Cables

For remote-sensor distances longer than 8 inches, or in particularly noisy environments, a twisted pair is recommended. Its practical length is 6 feet to 12 feet (typ) before noise becomes a problem, as tested in a noisy electronics laboratory. For longer distances, the best solution is a shielded twisted pair like that used for audio microphones. For example, Belden #8451 works well for distances up to 100 feet in a noisy environment. Connect the twisted pair to DXP and DXN and the shield to GND, and leave the shield's remote end unterminated.

Excess capacitance at DX_ limits practical remote-sensor distances (see *Typical Operating Characteristics*). For very long cable runs, the cable's parasitic capacitance often provides noise filtering, so the recommended 2200pF capacitor can often be removed or reduced in value.

Cable resistance also affects remote-sensor accuracy. A 1Ω series resistance introduces about $+1/2^\circ\text{C}$ error.

Programming Example: Clock-Throttling Control for CPUs

Listing 1 gives an untested example of pseudocode for proportional temperature control of Intel mobile CPUs through a power-management microcontroller. This program consists of two main parts: an initialization routine and an interrupt handler. The initialization routine checks for SMBus communications problems and sets up the MAX1618 configuration. The interrupt handler responds to $\overline{\text{ALERT}}$ signals by reading the current temperature and setting a CPU clock duty factor proportional to that temperature. The relationship between clock duty and temperature is fixed in a look-up table contained in the microcontroller code.

Note: Thermal management decisions should be made based on the latest external temperature obtained from the MAX1618 rather than the value of the Status Byte. The MAX1618 responds very quickly to changes in its environment due to its sensitivity and its small thermal mass. High and low alarm conditions can exist at the same time in the Status Byte, because the MAX1618 is correctly reporting environmental changes around it.
