Ehips<u>mall</u>

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

MAXM Low-Cost, Multiple-Output Power Supply for LCD TVs

General Description

The MAX17113 multiple-output power-supply controller generates all the supply rails for thin-film transistor (TFT) liquid-crystal display (LCD) panels in TVs and monitors operating from a regulated 12V input. It includes a step-down and a step-up regulator, a positive and a negative charge pump, a Dual Mode™ logiccontrolled high-voltage switch control block, and an adjustable-timing power-good output. The MAX17113 can operate from 8V to 16.5V input voltages and is optimized for LCD TV panel and LCD monitor applications running directly from 12V supplies.

The step-up and step-down regulators feature internal power MOSFETs and high-frequency operation allowing the use of small inductors and capacitors, resulting in a compact solution. Both switching regulators use fixed-frequency current-mode control architectures, providing fast load-transient response and easy compensation. A current-limit function for internal switches and output-fault shutdown protect the step-up and step-down power supplies against fault conditions. The MAX17113 provides soft-start functions to limit inrush current during startup. The MAX17113 provides adjustable power-up timing.

The positive and negative charge-pump regulators provide TFT gate-driver supply voltages. Both output voltages can be adjusted with external resistive voltagedividers. The switch control block allows the manipulation of the positive TFT gate-driver voltage.

A series p-channel MOSFET is integrated to sequence power to AVDD after the MAX17113 has proceeded through normal startup, and provides True Shutdown™.

The MAX17113 is available in a small (5mm x 5mm), low-profile (0.8mm), 40-pin thin QFN package and operates over a -40°C to +85°C temperature range.

Features

- ♦ **Optimized for 10.8V to 13.2V Input Supply**
- ♦ **8V to 16.5V Input Supply Range**
- ♦ **Selectable Frequency (450kHz/600kHz)**
- ♦ **Current-Mode Step-Up Regulator Built-In 24V, 3.3A, 80m**Ω **n-Channel MOSFET High-Accuracy Output Voltage (1%) True Shutdown Fast Load-Transient Response High Efficiency 10ms Internal Soft-Start**
- ♦ **Current-Mode Step-Down Regulator Built-In 24V, 3A, 100m**Ω **n-Channel MOSFET Fast Load-Transient Response Adjustable Output Voltage Down to 1.5V Skip Mode at Light Load (EN2 = AGND) High Efficiency 3ms Internal Soft-Start**
- ♦ **Adjustable Positive and Negative Charge-Pump Regulators**
- ♦ **Soft-Start and Timer-Delay Fault Latch for All Outputs**
- **Logic-Controlled High-Voltage Integrated Switches with Adjustable Delay**
- ♦ **120m**Ω **p-Channel FET for AVDD Sequencing**
- ♦ **Input Undervoltage Lockout and Thermal-Overload Protection**
- ♦ **40-Pin, 5mm x 5mm Thin QFN Package**

ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(Circuit of Figure 1, VVIN = VIN2 = 12V, **TA = 0°C to +85°C**. Typical values are at TA = +25°C, unless otherwise noted.)

Typical Operating Circuit

The typical operating circuit (Figure 1) of the MAX17113 is a complete power-supply system for TFT LCD panels in monitors and TVs. The circuit generates a +3.3V logic supply, a +16V source driver supply, a +34.5V positive gate driver supply, and a -6V negative gate driver supply from a $12V \pm 10\%$ input supply. Table 1 lists some selected components and Table 2 lists the contact information for component suppliers.

Table 1. Component List

Detailed Description

The MAX17113 is a multiple-output power supply designed primarily for TFT LCD panels used in monitors and TVs. It contains a step-down switching regulator to generate the logic supply rail, a step-up switching regulator to generate the source driver supply, and two charge-pump regulators to generate the gate driver supplies. Each regulator features adjustable output voltage, digital soft-start, and timer-delayed fault protection. Both the step-down and step-up regulators use a fixedfrequency current-mode control architecture. The two switching regulators are 180° out-of-phase to minimize the input ripple. The internal oscillator offers two pinselectable frequency options (450kHz/600kHz), allowing users to optimize their designs based on the specific application requirements. In addition, the MAX17113 features a high-voltage switch-control block, a PGOOD logic block, an internal 5V linear regulator, a 1.25V reference output, well-defined power-up and power-down sequences, and thermal-overload protection. Figure 2 shows the MAX17113 functional diagram.

Step-Down Regulator

The step-down regulator consists of an internal n-channel MOSFET with gate driver, a lossless current-sense network, a current-limit comparator, and a PWM controller block. The external power stage consists of a Schottky diode rectifier, an inductor, and output capacitors. The output voltage is regulated by changing the duty cycle of the n-channel MOSFET. A bootstrap circuit that uses a 0.1μF flying capacitor between LX2 and BST provides the supply voltage for the high-side gate driver. Although the MAX17113 also includes a 10Ω (typ) low-side MOSFET, this switch is used to charge the bootstrap capacitor during startup and maintains fixed-frequency operation at light load and cannot be used as a synchronous rectifier. An external Schottky diode (D2 in Figure 1) is always required.

Table 2. Component Suppliers

Figure 2. Functional Diagram

MAX1713

ATTITION

PWM Controller Block

The heart of the PWM control block is a multi-input, open-loop comparator that sums three signals: the output-voltage signal with respect to the reference voltage, the current-sense signal, and the slope compensation. The PWM controller is a direct-summing type, lacking a traditional error amplifier and the phase shift associated with it. This direct-summing configuration approaches ideal cycle-by-cycle control over the output voltage.

When EN1 and EN2 are high, the controller always operates in fixed-frequency PWM mode. Each pulse from the oscillator sets the main PWM latch that turns on the high-side switch until the PWM comparator changes state.

When EN1 is high and EN2 is low, the controller operates in skip mode. The skip mode dramatically improves light-load efficiency by reducing the effective frequency, which reduces switching losses. It keeps the peak inductor current at about 0.9A (typ) in an active cycle, allowing subsequent cycles to be skipped. Skip mode transitions seamlessly to fixedfrequency PWM operation as load current increases.

Current Limiting and Lossless Current Sensing

The current-limit circuit turns off the high-side MOSFET switch whenever the voltage across the high-side MOSFET exceeds an internal threshold. The actual current limit is 3A (typ).

For current-mode control, an internal lossless sense network derives a current-sense signal from the inductor DCR. The time constant of the current-sense network is not required to match the time constant of the inductor and has been chosen to provide sufficient current ramp signal for stable operation at both operating frequencies. The current-sense signal is AC-coupled into the PWM comparator, eliminating most DC outputvoltage variation with load current.

Low-Frequency Operation

The step-down regulator of the MAX17113 enters into low-frequency operating mode if the voltage on OUT is below 0.8V. In the low-frequency mode, the switching frequency of the step-down regulator is 1/6 the oscillator frequency. This feature prevents potentially uncontrolled inductor current if OUT is overloaded or shorted to ground.

Dual-Mode Feedback

The step-down regulator of the MAX17113 supports both fixed and adjustable output voltages. Connect FB2 to AGND to enable the 3.3V fixed output voltage. Connect a resistive voltage-divider between OUT and

AGND with the center tap connected to FB2 to adjust the output voltage. Choose RB (resistance from FB2 to AGND) to be between 5k Ω and 50k Ω , and solve for RA (resistance from OUT1 to FB1) using the equation:

$$
RA = RB \times \left(\frac{V_{OUT}}{V_{FB2}} \cdot 1\right)
$$

where $V_{FB2} = 1.25V$, and V_{OUT} can vary from 1.25V to 5V.

Because of FB2's (pin 17) close proximity to the noisy BST (pin 18), a noise filter is required for FB2 adjustable-mode operation. Place a 100pF capacitor from FB2 to AGND to prevent unstable operation. No filter is required for 3.3V fixed-mode operation.

Soft-Start

The step-down regulator includes a 7-bit soft-start DAC that steps its internal reference voltage from 0 to 1.25V in 128 steps. The soft-start period is 3ms (typ) and FB2 fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup (see the Step-Down Regulator Soft-Start (Heavy Load) waveforms in the Typical Operating Characteristics).

Step-Up Regulator

The step-up regulator employs a current-mode, fixedfrequency PWM architecture to maximize loop bandwidth and provide fast-transient response to pulsed loads typical of TFT LCD panel source drivers. The integrated MOSFET and the built-in digital soft-start function reduce the number of external components required while controlling inrush currents. The output voltage can be set from V_{IN} to 20V with an external resistive voltage-divider. The regulator controls the output voltage and the power delivered to the output by modulating the duty cycle (D) of the internal power MOSFET in each switching cycle. The duty cycle of the MOSFET is approximated by:

$$
D \approx \frac{V_{AVDD} - V_{IN}}{V_{AVDD}}
$$

where V_{AVDD} is the output voltage of the step-up regulator.

PWM Controller Block

An error amplifier compares the signal at FB1 to 1.25V and changes the COMP output. The voltage at COMP sets the peak inductor current. As the load varies, the error amplifier sources or sinks current to the COMP output accordingly to produce the inductor peak current necessary to service the load. To maintain stability at high duty cycles, a slope compensation signal is summed with the current-sense signal.

On the rising edge of the internal clock, the controller sets a flip-flop, turning on the n-channel MOSFET and applying the input voltage across the inductor. The current through the inductor ramps up linearly, storing energy in its magnetic field. Once the sum of the currentfeedback signal and the slope compensation exceed the COMP voltage, the controller resets the flip-flop and turns off the MOSFET. Since the inductor current is continuous, a transverse potential develops across the inductor that turns on the diode (D1). The voltage across the inductor then becomes the difference between the output voltage and the input voltage. This discharge condition forces the current through the inductor to ramp back down, transferring the energy stored in the magnetic field to the output capacitor and the load. The MOSFET remains off for the rest of the clock cycle.

Step-Up Regulator Internal p-Channel MOSFET Pass Switch

The MAX17113 includes an integrated 130mΩ highvoltage p-channel MOSFET to allow true shutdown of the step-up converter output (AVDD). This switch is typically connected in series between the step-up regulator's Schottky catch diode and its output capacitors. In addition to allowing step-up output to discharge completely when disabled, this switch also controls the startup inrush current into the step-up regulator's output capacitors.

Soft-Start

The step-up regulator includes a 7-bit soft-start DAC that steps its internal reference voltage from 0 to 1.25V in 128 steps. This DAC also controls linearly the gate of the pMOS switch, which is in between SWI and SWO, and the output AVDD goes up smoothly, and when the AVDD reaches the input voltage, the step-up regulator takes over seamlessly and the output-voltage AVDD reaches its regulation point. The soft-start period is 10ms (typ) and FB1 fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup.

Positive Charge-Pump Regulator

The positive charge-pump regulator is typically used to generate the positive supply rail for the TFT LCD gate driver ICs. The output voltage is set with an external resistive voltage-divider from its output to GND with the midpoint connected to FBP. The number of chargepump stages and the setting of the feedback divider determine the output voltage of the positive chargepump regulator. The charge pump includes a high-side p-channel MOSFET (P1) and a low-side n-channel MOSFET (N1) to control the power transfer as shown in Figure 3.

During the first half-cycle, N1 turns on and charges flying capacitors C20 and C21 (Figure 3). During the second half cycle, N1 turns off and P1 turns on, level shifting C20 and C21 by VAVDD volts. If the voltage across C23 plus a diode drop ($V_{\text{OUT}} + V_{\text{D}}$) is smaller than the level-shifted flying capacitor voltage (V_{C20} + VAVDD), charge flows from C20 to C23 until the diode (D5) turns off. The amount of charge transferred to the output is determined by the error amplifier that controls N1's on-resistance.

Figure 3. Positive Charge-Pump Regulator Block Diagram

MAX17113 **MAX17113**

The positive charge-pump regulator's startup can be delayed by connecting an external capacitor from DEL2 to AGND. An internal constant-current source begins charging the DEL2 capacitor when EN2 is logichigh, and the step-down regulator reaches regulation. When the DEL2 voltage exceeds VREF, the positive charge-pump regulator is enabled. Each time it is enabled, the positive charge-pump regulator goes through a soft-start routine by ramping up its internal reference voltage from 0 to 1.25V in 128 steps. The soft-start period is 3ms (typ) and FBP fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup.

Negative Charge-Pump Regulator

The negative charge-pump regulator is typically used to generate the negative supply rail for the TFT LCD gate driver ICs. The output voltage is set with an external resistive voltage-divider from its output to REF with the midpoint connected to FBN. The number of charge-pump stages and the setting of the feedback divider determine the output of the negative charge-pump regulator. The charge-pump controller includes a high-side p-channel MOSFET (P2) and a low-side n-channel MOSFET (N2) to control the power transfer as shown in Figure 4.

During the first half cycle, P2 turns on, and flying capacitor C13 charges to VIN minus a diode drop (Figure 4). During the second half cycle, P2 turns off, and N2 turns on, level shifting C13. This connects C13 in parallel with reservoir capacitor C12. If the voltage across C12 minus a diode drop is greater than the voltage across C13, charge flows from C12 to C13 until the diode (D3) turns off. The amount of charge transferred from the output is determined by the error amplifier, which controls N2's on-resistance.

The negative charge-pump regulator is enabled when EN1 is logic-high and the step-down regulator reaches regulation. Each time it is enabled, the negative charge-pump regulator goes through a soft-start routine by ramping down its internal reference voltage from 1.25V to 250mV in 102 steps. The soft-start period is 3ms (typ) and FBN fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup.

Figure 4. Negative Charge-Pump Regulator Block Diagram

High-Voltage Switch Control

The MAX17113's high-voltage switch control block (Figure 5) consists of two high-voltage p-channel MOSFETs: Q1, between SRC and GON and Q2, between GON and DRN. The switch control block is enabled when V_{DLP} exceeds V_{RFF}. Q1 and Q2 are controlled by CTL and MODE. There are two different modes of operation (see the Typical Operating Characteristics).

Select the first mode by connecting MODE to VL. When CTL is logic-high, Q1 turns on and Q2 turns off, connecting GON to SRC. When CTL is logic-low, Q1 turns off and Q2 turns on, connecting GON to DRN. GON can then be discharged through a resistor connected between DRN and GND or AV_{DD}. Q2 turns off and stops discharging GON when V_{GON} reaches 10 times the voltage on THR.

Figure 5. Switch Control

MAXIM

When V_{MODE} is less than 0.8 x V_{VL} , the switch control block works in the second mode. The rising edge of V_{CTL} turns on Q1 and turns off Q2, connecting GON to SRC. An internal n-channel MOSFET, Q3, between MODE and AGND is also turned on to discharge an external capacitor between MODE and AGND. The falling edge of VCTL turns off Q3, and an internal 50µA current source starts charging the MODE capacitor. Once VMODE exceeds VVL/4, the switch control block turns off Q1 and turns on Q2, connecting GON to DRN. GON can then be discharged through a resisor connected between DRN and PGND or AVDD. Q2 turns off and stops discharging GON when V_{GON} reaches 10 times the voltage on THR.

The switch control block is disabled and DLP is held low when EN1 or EN2 is low or the IC is in a fault state.

Linear Regulator (VL)

The MAX17113 includes an internal linear regulator. VIN is the input of the linear regulator. The input voltage range is between 8V and 16.5V. The output voltage is set to 5V. The regulator powers the internal MOSFET drivers, PWM controllers, charge-pump regulators, and logic circuitry. The total external load capability is 25mA. Bypass VL to AGND with a minimum 1μF ceramic capacitor.

Reference Voltage (REF)

The reference output is nominally 1.25V, and can source at least 50μA (see the Typical Operating Characteristics). VL is the input of the internal reference block. Bypass REF with a 0.22μF ceramic capacitor connected between REF and AGND.

Frequency Selection (FSEL)

The step-down regulator and step-up regulator use the same internal oscillator. The FSEL input selects the switching frequency. Table 3 shows the switching frequency based on the FSEL connection. High-frequency (600kHz) operation optimizes the application for the smallest component size, trading off efficiency due to higher switching losses. Low-frequency (450kHz) operation offers the best overall efficiency at the expense of component size and board space.

Table 3. Frequency Selection

Power-Up Sequence

The step-down regulator starts up when the MAX17113's internal reference voltage (REF) is above its undervoltage lockout (UVLO) threshold and EN1 is logic-high.

Once the step-down regulator reaches regulation, the FB2 fault-detection circuit and the negative chargepump delay block are enabled. An 8μA current source at DEL1 charges C_{DEL1} linearly. The negative chargepump regulator soft-starts when V_{DEL1} reaches VREF. FBN fault detection is enabled once the negative charge-pump soft-start is done. See Figure 6.

The step-up regulator, p-channel MOSFET pass switch, and positive charge-pump startup sequence begin when the step-down regulator reaches regulation and EN2 is logic-high. An 8μA current source at DEL2 charges C_{DEL2} linearly and the positive charge pump is enabled when V_{DEL2} reaches V_{REF} . When the positive charge pump is in regulation, an 8μA current source charges C_{DLP} linearly and when V_{DLP} reaches VREF, the high-voltage switch is enabled and GON can be controlled by CTL.

The FB1 fault-detection circuit is enabled after the stepup regulator reaches regulation, and similarly the FBP fault-detection circuit is enabled after the positive charge pump reaches regulation. For nondelayed startups, capacitors can be omitted from DEL1, DEL2, and DLP. When their current sources pull the pins above their thresholds, the associated outputs start.

Power-Down Control

The MAX17113 disables the step-up regulator, positivecharge-pump regulator input switch control block, delay block, and high-voltage switch control block when EN2 is logic-low, or when the fault latch is set. The step-down regulator and negative charge-pump regulator are disabled only when EN1 is logic-low or when the fault latch is set.

Fault Protection

During steady-state operation, if any output of the four regulators (step-down regulator, step-up regulator, positive charge-pump regulator, and negative chargepump regulator) does not exceed its respective faultdetection threshold, the MAX17113 activates an internal fault timer. If any condition or the combination of conditions indicates a continuous fault for the fault timer duration (50ms, typ), the MAX17113 triggers a nonlatching output undervoltage fault. After triggering, the MAX17113 turns off for 160ms (typ) and then restarts according to the EN1 and EN2 logic states. If, after restarting, another 50ms fault timeout occurs, the MAX17113 shuts down for 160ms again, and then restarts. The restart sequence is repeated 3 times and after the 50ms fault timeout, the MAX17113 shuts down and latches off. Once the fault condition is removed, toggle either EN1 or EN2, or cycle the input voltage to clear the fault latch and restart the supplies.

__ 23

MAXIM

MAX1713

MAX17113

Thermal-Overload Protection

The thermal-overload protection prevents excessive power dissipation from overheating the MAX17113. When the junction temperature exceeds $T_{\text{J}} = +160^{\circ}$ C, a thermal sensor immediately activates the fault protection that shuts down all the outputs except the reference and latches off, allowing the device to cool down. Once the device cools down by at least approximately 15°C, cycle the input voltage to clear the fault latch and restart the MAX17113.

The thermal-overload protection protects the controller in the event of fault conditions. For continuous operation, do not exceed the absolute maximum junction temperature rating of $T_{\rm J}$ = +150°C.

Design Procedure

Step-Down Regulator

Inductor Selection

Three key inductor parameters must be specified: inductance value (L), peak current (IPEAK), and DC resistance (R_{DC}). The following equation includes a constant, LIR, which is the ratio of peak-to-peak inductor ripple current to DC load current. A higher LIR value allows smaller inductance, but results in higher losses and higher ripple. A good compromise between size and losses is typically found at about 20% to 50% ripple-current to load-current ratio (LIR):

$$
L_{OUT} = \frac{V_{OUT} \times (V_{IN2} - V_{OUT})}{V_{IN2} \times f_{SW} \times I_{OUT(MAX)} \times LIR}
$$

where $I_{\text{OUT}(MAX)}$ is the maximum DC load current, and the switching frequency fsw is 600kHz when FSEL is connected to VL or 450kHz when FSEL is connected to AGND. The exact inductor value is not critical and can be adjusted to make trade-offs among size, cost, and efficiency. Lower inductor values minimize size and cost, but they also increase the output ripple and reduce the efficiency due to higher peak currents. On the other hand, higher inductor values increase efficiency, but at some point resistive losses due to extra turns of wire exceed the benefit gained from lower AC current levels.

The inductor's saturation current must exceed the peak inductor current. The peak current can be calculated by:

$$
V_{OUT_RIPPLE} = \frac{V_{OUT} \times (V_{IN2} - V_{OUT})}{f_{SW} \times L_{OUT} \times V_{IN2}}
$$

$$
V_{OUT_PEAK} = V_{OUT(MAX)} + \frac{V_{OUT_RIPPLE}}{2}
$$

The inductor's DC resistance should be low for good efficiency. Find a low-loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. Ferrite cores are often the best choice. Shieldedcore geometries help keep noise, EMI, and switching waveform jitter low.

Considering the typical operating circuit in Figure 1, the maximum load current ($I_{\text{OUT}(MAX)}$) is 2A with a 3.3V output and a typical 12V input voltage. Choosing an LIR of 0.4 at this operating point:

$$
L_{OUT} = \frac{3.3V \times (12V - 3.3V)}{12V \times 600kHz \times 2A \times 0.4} \approx 5.0 \mu H
$$

At that operating point, the ripple current and the peak current are:

$$
I_{OUT_RIPPLE} = \frac{3.3V \times (12V - 3.3V)}{600kHz \times 5.0\mu H \times 12} \approx 0.8A
$$

$$
I_{OUT_PEAK} = 2A + \frac{0.8A}{2} = 2.4A
$$

Input Capacitors

The input filter capacitors reduce peak currents drawn from the power source and reduce noise and voltage ripple on the input caused by the regulator's switching. They are usually selected according to input ripple current requirements and voltage rating, rather than capacitance value. The input voltage and load current determine the RMS input ripple current (IRMS):

$$
I_{RMS} = I_{OUT} \times \frac{\sqrt{V_{OUT} \times (V_{IN2} - V_{OUT})}}{V_{IN2}}
$$

The worst case is $I_{RMS} = 0.5 \times I_{OUT}$, which occurs at V IN2 = $2 \times V$ OUT.

For most applications, ceramic capacitors are used because of their high ripple current and surge current capabilities. For optimal circuit long-term reliability, choose an input capacitor that exhibits less than +10°C temperature rise at the RMS input current corresponding to the maximum load current.

Output Capacitor Selection

Since the MAX17113's step-down regulator is internally compensated, it is stable with any reasonable amount of output capacitance. However, the actual capacitance and equivalent series resistance (ESR) affect the regulator's output ripple voltage and transient response. The rest of this section deals with how to determine the output capacitance and ESR needs according to the ripple-voltage and load-transient requirements.

The output-voltage ripple has two components: variations in the charge stored in the output capacitor, and the voltage drop across the capacitor's ESR caused by the current into and out of the capacitor:

VOUT RIPPLE = V_{OUT} RIPPLE(ESR) + V_{OUT} RIPPLE(C)

 V_{OUT} RIPPLE(ESR) = V_{OUT} RIPPLE \times RESR OUT

$$
V_{OUT_RIPPLE(C)} = \frac{I_{OUT_RIPPLE}}{8 \times C_{OUT} \times f_{SW}}
$$

where $I_{\text{OUT_RIPPLE}}$ is defined in the *Inductor Selection* of the Step-Down Regulator section, COUT is the output capacitance, and R_{ESR} OUT is the ESR of the output capacitor C_{OUT} . In Figure 1's circuit, the inductor ripple current is 0.8A. If the voltage-ripple requirement of Figure 1's circuit is $\pm 1\%$ of the 3.3V output, then the total peak-to-peak ripple voltage should be less than 66mV. Assuming that the ESR ripple and the capacitive ripple each should be less than 50% of the total peakto-peak ripple, then the ESR should be less than 43mΩ and the output capacitance should be more than 5μF to meet the total ripple requirement. A 22μF capacitor with ESR (including PCB trace resistance) of $10 \text{m}\Omega$ is selected for the standard application circuit in Figure 1, which easily meets the voltage-ripple requirement.

The step-down regulator's output capacitor and ESR can also affect the voltage undershoot and overshoot when the load steps up and down abruptly. The step-down regulator's transient response is typically dominated by its loop response and the time constant of its internal integrator. However, excessive inductance or insufficient output capacitance can degrade the natural transient response. Calculating the ideal transient response of the inductor and capacitor, which assumes an ideal response from the regulator, can ensure that these components do not degrade the IC's natural response.

The ideal undershoot and overshoot have two components: the voltage steps caused by ESR, and the voltage sag and soar due to the finite capacitance and the inductor current slew rate. Use the following formulas to check if the ESR is low enough and the output capacitance is large enough to prevent excessive soar and sag.

The amplitude of the ESR step is a function of the load step and the ESR of the output capacitor:

 V_{OUT} ESR STEP = $\Delta I_{\text{OUT}} \times R_{\text{ESR}}$ out

The amplitude of the capacitive sag is a function of the load step, the output capacitor value, the inductor value, the input-to-output voltage differential, and the maximum duty cycle:

 V_{OUT} $SAG = \frac{L_{\text{OUT}} \times (\Delta I)}{L_{\text{OUT}}}$ $\gamma_{\rm OUT_SAG} = \frac{\text{LOUT} \times (\Delta \text{OUT})}{2 \times \text{C}_{\text{OUT}} \times (\text{V_{INIMIN})} \times \text{D}}$ OUT ^X (^vIN(MIN) ^{X D}MAX _ (MIN) $=\frac{L_{OUT} \times (\Delta I_{OUT})}{\Delta I_{OUT} \times (\Delta I_{OUT})}$ \times C_{OUT} \times (V_{IN(MIN)} \times [Δ \vert_{OUT})² $2\times C_{\text{OUT}}\times \left(\mathsf{V}_{\mathsf{IN}(\mathsf{MIN})}\times \mathsf{D}_{\text{MAX}}\cdot \mathsf{V}_{\text{OUT}}\right)$

The amplitude of the capacitive soar is a function of the load step, the output capacitor value, the inductor value, and the output voltage:

$$
V_{\text{OUT_SOAR}} = \frac{L_{\text{OUT}} \times (\Delta I_{\text{OUT}})^2}{2 \times C_{\text{OUT}} \times V_{\text{OUT}}}
$$

Keeping the full-load overshoot and undershoot less than 3% ensures that the step-down regulator's natural integrator response dominates. Given the component values in the circuit of Figure 1 and assuming a full 1.5A step load transient, the voltage step due to capacitor ESR is negligible. The voltage sag and soar are 76mV and 73mV, or a little over 1% and 2%, respectively.

Rectifier Diode

The MAX17113's high switching frequency demands a high-speed rectifier. Schottky diodes are recommended for most applications because of their fast recovery time and low forward voltage. In general, a 2A Schottky diode works well in the MAX17113's step-down regulator.

Step-Up Regulator

Inductor Selection

The inductance value, peak current rating, and series resistance are factors to consider when selecting the inductor. These factors influence the converter's efficiency, maximum output load capability, transient response time, and output-voltage ripple. Physical size and cost are also important factors to be considered.

The maximum output current, input voltage, output voltage, and switching frequency determine the inductor value. Very high inductance values minimize the current ripple, and therefore, reduce the peak current, which decreases core losses in the inductor and I2R losses in the entire power path. However, large inductor values also require more energy storage and more turns of wire that increase physical size and can increase I2R losses in the inductor. Low inductance values decrease the physical size, but increase the current ripple and peak current. Finding the best inductor involves choosing the best compromise among circuit efficiency, inductor size, and cost.

The equations used here include a constant, LIR, which is the ratio of the inductor peak-to-peak ripple current to the average DC inductor current at the full-load current. The best trade-off between inductor size and circuit efficiency for step-up regulators generally has an LIR between 0.2 and 0.5. However, depending on the AC
