

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

**MAXIM****Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs****General Description**

The MAX5180 contains two 10-bit, simultaneous-update, current-output digital-to-analog converters (DACs) designed for superior performance in communications systems requiring analog signal reconstruction with low distortion and low-power operation. The MAX5183 provides equal specifications, with on-chip precision resistors for voltage output operation. The devices are designed for 10pVs glitch operation to minimize unwanted spurious signal components at the output. An on-board 1.2V bandgap circuit provides a well-regulated, low-noise reference that can be disabled for external reference operation.

The MAX5180/MAX5183 are designed to provide a high level of signal integrity for the least amount of power dissipation. The DACs operate from a single supply of 2.7V to 3.3V. Additionally, these DACs have three modes of operation: normal, low-power standby, and complete shutdown, which provides the lowest possible power dissipation with 1 $\mu$ A (max) shutdown current. A fast wake-up time (0.5 $\mu$ s) from standby mode to full DAC operation conserves power by activating the DACs only when required.

The MAX5180/MAX5183 are packaged in a 28-pin QSOP and are specified for the extended (-40°C to +85°C) temperature range. For lower-resolution, dual 8-bit versions, refer to the MAX5186/MAX5189 data sheet.

**Applications**

Signal Reconstruction of I and Q Transmit Signals  
Digital Signal Processing  
Arbitrary Waveform Generation (AWG)  
Imaging

**Features**

- ◆ 2.7V to 3.3V Single-Supply Operation
- ◆ Wide Spurious-Free Dynamic Range: 70dB at  $f_{OUT} = 2.2\text{MHz}$
- ◆ Fully Differential Outputs for Each DAC
- ◆  $\pm 0.5\%$  FSR Gain Mismatch
- ◆  $\pm 0.2^\circ$  Phase Mismatch
- ◆ Low-Current Standby or Full-Shutdown Modes
- ◆ Internal 1.2V Low-Noise Bandgap Reference
- ◆ Small 28-Pin QSOP Package

**MAX5180/MAX5183**

# **Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs**

Figure 1. Functional Diagram

## ***Detailed Description***

The MAX5180/MAX5183 are dual, 10-bit digital-to-analog converters (DACs) capable of operating with clock speeds up to 40MHz. Each of these dual converters consists of separate input and DAC registers, followed by a current source array capable of generating up to 1.5mA full-scale output current (Figure 1). An integrated 1.2V voltage reference and control amplifier determine the data converters' full-scale output currents/voltages. Careful reference design ensures close gain matching and excellent drift characteristics. The MAX5183's voltage output operation features matched  $400\Omega$  on-chip resistors that convert the current array current into a voltage.

## ***Internal Reference and Control Amplifier***

The MAX5180/MAX5183 provide an integrated 50ppm/ $^{\circ}\text{C}$ , 1.2V, low-noise bandgap reference that can be disabled and overridden by an external reference voltage. REFO serves either as an external reference input or an integrated reference output. If  $\overline{\text{REN}}$  is connected to AGND, the internal reference is selected and REFO provides a 1.2V output. Due to its limited 10 $\mu\text{A}$

output drive capability, REFO must be buffered with an external amplifier, if heavier loading is required.

The MAX5180/MAX5183 also employ a control amplifier designed to simultaneously regulate the full-scale output current ( $I_{FS}$ ) for both outputs of the devices. The output current is calculated as follows:

$$|_{FS} = 8 \times |_{REF}$$

where  $I_{REF}$  is the reference output current ( $I_{REF} = V_{REF0}/R_{SET}$ ) and  $I_F$  is the full-scale output current.  $R_{SET}$  is the reference resistor that determines the amplifier's output current on the MAX5180 (Figure 2). This current is mirrored into the current-source array where it is equally distributed between matched current segments and summed to valid output current readings for the DACs.

The MAX5183 converts each output current (DAC1 and DAC2) into an output voltage ( $V_{OUT1}$ ,  $V_{OUT2}$ ) with two internal, ground-referenced  $400\Omega$  load resistors. Using the internal 1.2V reference voltage, the MAX5183's integrated reference output current resistor ( $R_{SET} = 9.6\text{k}\Omega$ ) sets  $I_{REF}$  to  $125\mu\text{A}$  and  $I_{FS}$  to  $1\text{mA}$ .

# Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs

MAX5180/MAX5183

Figure 3. MAX5180/MAX5183 with External Reference

# Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs

## External Reference

To disable the MAX5180/MAX5183's internal reference, connect  $\overline{REN}$  to AVDD. A temperature-stable, external reference may now be applied to drive the REFO pin to set the full-scale output (Figure 3). Choose a reference capable of supplying at least 150 $\mu$ A to drive the bias circuit that generates the cascode current for the current array. For improved accuracy and drift performance, choose a fixed output voltage reference such as the 1.2V, 25ppm/ $^{\circ}$ C MAX6520 bandgap reference.

## Standby Mode

To enter the lower power standby mode, connect digital inputs PD and DACEN to DGND. In standby, both the reference and the control amplifier are active with the current array inactive. To exit this condition, DACEN must be pulled high with PD held at DGND. Both the

MAX5180 and MAX5183 typically require 50 $\mu$ s to wake up and allow both the outputs and the reference to settle.

## Shutdown Mode

For lowest power consumption, the MAX5180/MAX5183 provide a power-down mode in which the reference, control amplifier, and current array are inactive and the DAC supply current is reduced to 1 $\mu$ A. To enter this mode, connect PD to DVDD. To return to active mode, connect PD to DGND and DACEN to DVDD. Table 1 lists the power-down mode selection. About 50 $\mu$ s are required for the parts to leave shutdown mode and settle to their outputs' values prior to shutdown.

## Timing Information

The MAX5180/MAX5183 dual DACs write to their outputs simultaneously (Figure 4). On the falling edge of

Figure 4. Timing Diagram

Table 1. Power-Down Mode Selection

PD (POWER-DOWN SELECT)	DACEN (DAC ENABLE)	POWER-DOWN MODE	OUTPUT STATE	
0	0	Standby	MAX5180	High-Z
			MAX5183	AGND
0	1	Wake-Up	Last state prior to standby mode	
1	X	Shutdown	MAX5180	High-Z
			MAX5183	AGND

X = Don't care

# Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs

MAX5180/MAX5183

the clock, the input data for DAC2 is preloaded into a latch. On the rising edge of the clock, input data for DAC1 is loaded to the DAC1 register, and the pre-loaded DAC2 data in the latch is loaded to the DAC2 register.

## Outputs

The MAX5180 outputs are designed to supply full-scale output currents of 1mA into  $400\Omega$  loads in parallel with a capacitive load of 5pF. The MAX5183 features integrated  $400\Omega$  resistors that restore the array currents to proportional, differential voltages of 400mV. These differential output voltages can then be used to drive a balun transformer or a low-distortion, high-speed operational amplifier to convert the differential voltage into a single-ended voltage.

## Applications Information

### Static and Dynamic Performance Definitions

#### Integral Nonlinearity (INL)

Integral nonlinearity is the deviation of the values on an actual transfer function from either a best straight-line fit (closest approximation to the actual transfer curve) or a line drawn between the end points of the transfer function, once offset and gain errors have been nullified. The MAX5180/MAX5183 use a straight-line end-point fit for INL (and DNL) and the deviations are measured at every individual step.

#### Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between an actual step height and the ideal value of 1 LSB. A DNL error specification no more negative than -1 LSB guarantees a monotonic transfer function.

#### Offset Error

The offset error is the difference between the ideal and the actual offset current/voltage. For the MAX5180/MAX5183, the offset error is the midpoint value of the transfer function determined by the end points of a straight-line end-point fit. This error affects all codes by the same amount.

#### Gain Error

Gain error is the difference between the ideal and the actual output value range. This range represents the output when all digital inputs are set to 1 minus the output when all digital inputs are set to zero.

#### Glitch Impulse

A glitch is generated when a DAC switches between two codes. The largest glitch is usually generated

around the midscale transition when the input pattern transitions from 011...111 to 100...000. This occurs due to timing variations between the bits. The glitch impulse is found by integrating the voltage of the glitch at the midscale transition over time. The glitch impulse is usually specified in pV-s.

#### Settling Time

The settling time is the amount of time required from the start of a transition until the DAC output settles its new output value to within the converter's specified accuracy.

#### Digital Feedthrough

Digital feedthrough is the noise generated on a DAC's output when any digital input transitions. Proper board layout and grounding will significantly reduce this noise, but there will always be some feedthrough caused by the DAC itself.

#### Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of the input signal's first four harmonics to the fundamental itself. This is expressed as:

$$\text{THD} = 20 \times \log \left( \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2}}{V_1} \right)$$

where  $V_1$  is the fundamental amplitude, and  $V_2$  through  $V_5$  are the amplitudes of the 2nd- through 5th-order harmonics.

#### Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio of RMS amplitude of the carrier frequency (maximum signal component) to the RMS value of the next-largest noise or harmonic distortion component. SFDR is usually measured in dBc with respect to the carrier frequency amplitude or in dBFS with respect to the DAC's full-scale range. Depending on its test condition, SFDR is observed within a predefined window or to Nyquist. In the case of the MAX5180/MAX5183, the SFDR performance is measured for a 0dBFS output amplitude and analyzed within the Nyquist window.

#### Differential to Single-Ended Conversion

The MAX4108 low-distortion, high-input bandwidth amplifier may be used to generate a voltage from the array current output of the MAX5180. The differential voltage across OUT1P (or OUT2P) and OUT1N (or OUT2N) is converted into a single-ended voltage by designing an appropriate operational amplifier configuration (Figure 5).

## Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs

Figure 5. Differential to Single-Ended Conversion Using a Low-Distortion Amplifier

### I/Q Reconstruction in a QAM Application

The MAX5180/MAX5183's low-distortion supports analog reconstruction of in-phase (I) and quadrature (Q) carrier components typically used in QAM (quadrature amplitude modulation) architectures where I and Q data are interleaved on a common data bus. A QAM signal is a carrier frequency that is both amplitude and phase modulated, and is created by summing two independently modulated carriers of identical frequency but different phase (90° phase difference).

In a typical QAM application (Figure 6), the modulation occurs in the digital domain and the MAX5180/MAX5183's dual DACs may be used to reconstruct the analog I and Q components.

The I/Q reconstruction system is completed by a quadrature modulator that combines the reconstructed I and Q components with in-phase and quadrature phase carrier frequencies, then sums both outputs to provide the QAM signal.

### Grounding and Power-Supply Decoupling

Grounding and power-supply decoupling strongly influence the MAX5180/MAX5183's performance. Unwanted digital crosstalk may couple through the input, reference, power-supply, and ground connections, which may affect dynamic specifications like signal-to-noise ratio or spurious-free dynamic range. In addition, electromagnetic interference (EMI) can either couple into or be generated by the MAX5180/MAX5183. Therefore,

## **Dual, 10-Bit, 40MHz, Current/Voltage Simultaneous-Output DACs**

**MAX5180/MAX5183**

Figure 6. Using the MAX5180/MAX5183 for I/Q Signal Reconstruction

grounding and power-supply decoupling guidelines for high-speed, high-frequency applications should be closely followed.

First, a multilayer pc board with separate ground and power-supply planes is recommended. High-speed signals should be run on controlled impedance lines directly above the ground plane. Since the MAX5180/MAX5183 have separate analog and digital ground buses (AGND and DGND, respectively), the PC board should also have separate analog and digital ground sections with only one point connecting the two. Digital signals should run above the digital ground plane, and analog signals should run above the analog ground plane.

Both devices have two power-supply inputs: analog VDD (AVDD) and digital VDD (DVDD). Each AVDD input should be decoupled with parallel  $10\mu\text{F}$  and  $0.1\mu\text{F}$  ceramic-chip capacitors. These capacitors should be as close to the pin as possible, and their opposite ends should be as close to the ground plane as possible. The

DVDD pins should also have separate  $10\mu\text{F}$  and  $0.1\mu\text{F}$  capacitors adjacent to their respective pins. Try to minimize analog load capacitance for proper operation. For best performance, it is recommended to bypass CREF1 and CREF2 with low-ESR  $0.1\mu\text{F}$  capacitors to AVDD.

The power-supply voltages should also be decoupled with large tantalum or electrolytic capacitors at the point they enter the PC board. Ferrite beads with additional decoupling capacitors forming a pi network can also improve performance.
