Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

MAXIM

µP Supervisory Circuits with Windowed (Min/Max) Watchdog and Manual Reset

MAX6323/MAX6324

General Description

The MAX6323/MAX6324 microprocessor (µP) supervisory circuits monitor power supplies and µP activity in digital systems. A watchdog timer looks for activity outside an expected window of operation. Six laser-trimmed reset thresholds are available with ±2.5% accuracy from +2.32V to +4.63V. Valid $\overline{RESET}$ output is guaranteed down to V_{CC} = +1.2V.

The $\overline{RESET}$ output is either push-pull (MAX6323) or open-drain (MAX6324). $\overline{RESET}$ is asserted low when V_{CC} falls below the reset threshold, or when the manual reset input ($\overline{MR}$) is asserted low. $\overline{RESET}$ remains asserted for at least 100ms after V_{CC} rises above the reset threshold and $\overline{MR}$ is deasserted.
The watchdog pulse output ($\overline{WDPO}$) utilizes an open-drain configuration. It can be triggered either by a fast timeout fault (watchdog input pulses are too close to each other) or a slow timeout fault (no watchdog input pulse is observed within the timeout period). The watchdog timeout is measured from the last falling edge of watchdog input (WDI) with a minimum pulse width of 300ns. $\overline{WDPO}$ is asserted for 1ms when a fault is observed. Eight laser-trimmed timeout periods are available.

The MAX6323/MAX6324 are offered in a 6-pin SOT23 package and operate over the extended temperature range (-40°C to +125°C).

Applications

Automotive

Industrial

Medical

Embedded Control Systems

Features

♦ **Min/Max (Windowed) Watchdog, 8 Factory-Trimmed Timing Options**

♦ **Pulsed Open-Drain, Active-Low Watchdog Output**

♦ **Power-On Reset**

♦ **Precision Monitoring of +2.5V, +3.0V, +3.3V, and +5.0V Power Supplies**

♦ **Open-Drain or Push-Pull $\overline{RESET}$ Outputs**

♦ **Low-Power Operation (23µA typ)**

♦ **Debounced Manual Reset Input**

♦ **Guaranteed Reset Valid to V_{CC} = +1.2V**

Pin Description

PIN	NAME	FUNCTION
1	$\overline{\text{MR}}$	Active-Low, Manual Reset Input. When $\overline{\text{MR}}$ is asserted low, $\overline{\text{RESET}}$ is asserted low, the internal watchdog timer is reset to zero, and $\overline{\text{WDPO}}$ is reset to high impedance (open drain). After the rising edge of $\overline{\text{MR}}$, $\overline{\text{RESET}}$ is asserted for at least 100ms. Leave $\overline{\text{MR}}$ unconnected or connect to V$_{CC}$ if unused.
2	GND	Ground
3	WDI	Watchdog Input. The internal watchdog timer clears to zero on the falling edge of WDI or when $\overline{\text{RESET}}$ goes high. If WDI sees another falling edge within the factory-trimmed watchdog window, $\overline{\text{WDPO}}$ will remain unasserted. Transitions outside this window, either faster or slower, will cause $\overline{\text{WDPO}}$ to pulse low for 1ms (typ).
4	V$_{CC}$	Supply Voltage for the Device. Input for V$_{CC}$ reset monitor. For noisy systems, bypass V$_{CC}$ with a 500pF (min) capacitor.
5	$\overline{\text{WDPO}}$	Watchdog Pulse Output. The open-drain $\overline{\text{WDPO}}$ output is pulsed low for 1ms (typ) upon detection of a fast or slow watchdog fault. $\overline{\text{WDPO}}$ is only active when $\overline{\text{RESET}}$ is high.
6	$\overline{\text{RESET}}$	Active-Low. Reset is asserted when V$_{CC}$ drops below V$_{TH}$ and remains asserted until V$_{CC}$ rises above V$_{TH}$ for the duration of the reset timeout period. The MAX6323 has a push-pull output and the MAX6324 has an open-drain output. Connect a pullup resistor from $\overline{\text{RESET}}$ to any supply voltage up to +6V.

Figure 1. Detailed Watchdog Input Timing Relationship

Detailed Description

The MAX6323/MAX6324 µP supervisory circuits maintain system integrity by alerting the µP to fault conditions. In addition to a standard V_{CC} monitor (for power-on reset, brownout detect, and power-down reset), the devices include a sophisticated watchdog timer that detects when the processor is running outside an expected window of operation for a specific application. The watchdog signals a fault when the input pulses arrive too early (faster than the selected t_{WD1} timeout period) or too late (slower than the selected t_{WD2} timeout period) (Figure 1). Incorrect timing can lead to poor or dangerous system performance in tightly controlled operating environments. Incorrect timing could be the result of improper µP clocking or code execution errors. If a timing error occurs, the MAX6323/MAX6324 issue a watchdog pulse output, independent from the reset output, indicating that system maintenance may be required.

Watchdog Function

A pulse on the watchdog output $\overline{WDPO}$ can be triggered by a fast fault or a slow fault. If the watchdog input (WDI) has two falling edges too close to each other (faster than t_{WD1}) (Figure 2) or falling edges that are too far apart (slower than t_{WD2}) (Figure 3), $\overline{WDPO}$ is pulsed low. Normal watchdog operation is displayed in Figure 4 ($\overline{WDPO}$ is not asserted). The internal watchdog timer is cleared when a WDI falling edge is detected within the valid watchdog window or when the device's $\overline{RESET}$ or $\overline{WDPO}$ outputs are deasserted. All WDI input pulses are ignored while either $\overline{RESET}$ or $\overline{WDPO}$ is asserted. Figure 1 identifies the input timing regions where $\overline{WDPO}$ fault outputs will be observed with respect to t_{WD1} and t_{WD2}. After $\overline{RESET}$ or $\overline{WDPO}$ deasserts, the first WDI falling edge is ignored for the fast fault condition (Figure 2).

Upon detecting a watchdog fault, the $\overline{WDPO}$ output will pulse low for 1ms. $\overline{WDPO}$ is an open-drain output. Connect a pullup resistor on $\overline{WDPO}$ to any supply up to +6V.

V_{CC} Reset

The MAX6323/MAX6324 also include a standard V_{CC} reset monitor to ensure that the µP is started in a known state and to prevent code execution errors during power-up, power-down, or brownout conditions. $\overline{RESET}$ is asserted whenever the V_{CC} supply voltage

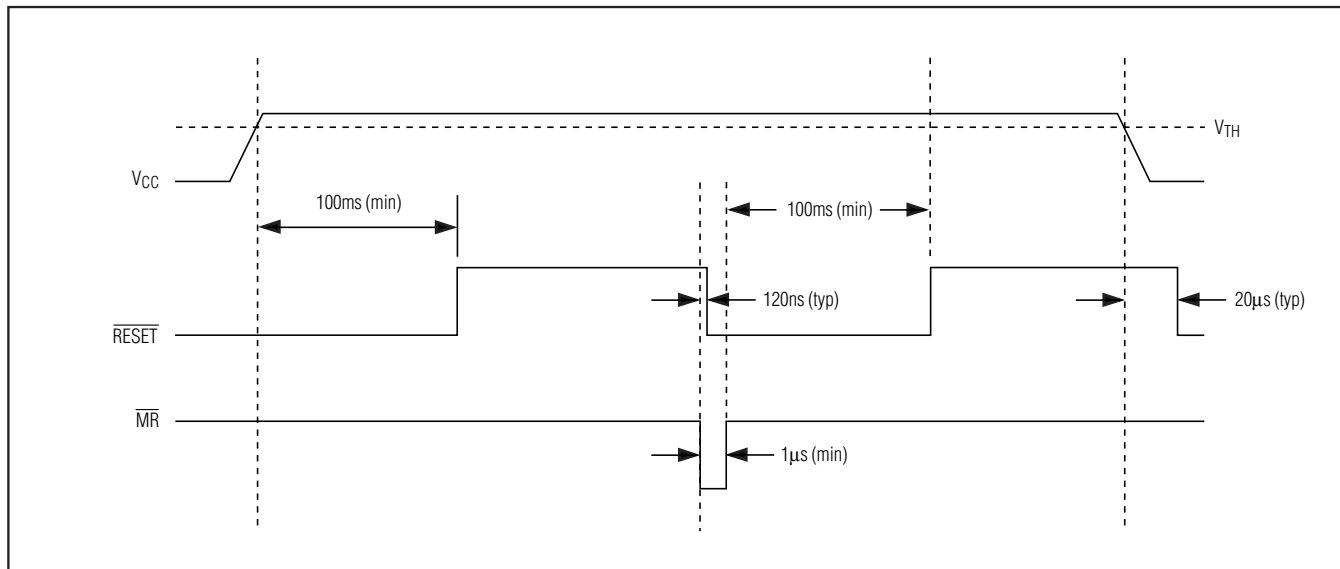

Figure 5. RESET Timing Relationship

falls below the preset threshold or when the manual reset input (MR) is asserted. The RESET output remains asserted for at least 100ms after V_CC has risen above the reset threshold and MR is deasserted (Figure 5). For noisy environments, bybass V_CC with a 500pF (min) capacitor to ensure correct operation.

The MAX6323 has a push-pull output stage, and the MAX6324 utilizes an open-drain output. Connect a pull-up resistor on the RESET output of the MAX6324 to any supply up to +6V. Select a resistor value large enough to register a logic low (see *Electrical Characteristics*) and small enough to register a logic high while supplying all input leakage currents and leakage paths connected to the RESET line. A 10kΩ pullup is sufficient in most applications.

Manual Reset Input
Many µP-based products require manual reset capability to allow an operator or external logic circuitry to initiate a reset. The manual reset input (MR) can connect directly to a switch without an external pullup resistor or debouncing network. MR is internally pulled up to V_CC and, therefore, can be left unconnected if unused. MR is designed to reject fast, negative-going transients (typically 100ns pulses), and it must be held low for a minimum of 1µs to assert the reset output (Figure 5). A 0.1µF capacitor from MR to ground provides additional noise immunity. After MR transitions from low to high, reset will remain asserted for the duration of the reset timeout period, at least 100ms.

Applications Information

Negative-Going V_CC Transients
The MAX6323/MAX6324 are relatively immune to short-duration negative-going V_CC transients (glitches), which usually do not require the entire system to shut down. Typically, 200ns large-amplitude pulses (from ground to V_CC) on the supply will not cause a reset. Lower amplitude pulses result in greater immunity. Typically, a V_CC transient that falls 100mV below the reset threshold and lasts less than 20µs will not trigger a reset (see *Typical Operating Characteristics*). An optional 0.1µF bypass capacitor mounted close to V_CC provides additional transient immunity.

Ensuring a Valid Reset Output Down to V_CC = 0V
When V_CC falls below +1.2V, the MAX6323 RESET output no longer sinks current; it becomes an open circuit. Therefore, high-impedance CMOS logic inputs connected to RESET can drift to undetermined voltages. This does not present a problem in most applications, since most µPs and other circuitry are inoperative with V_CC below +1.2V. However, in applications where RESET must be valid down to 0, adding a pulldown resistor to RESET causes any stray leakage currents to flow to ground, holding RESET low (Figure 6). R1's value is not critical; 100kΩ is large enough not to load RESET and small enough to pull RESET to ground. This scheme does not work with the open-drain output of the MAX6324.
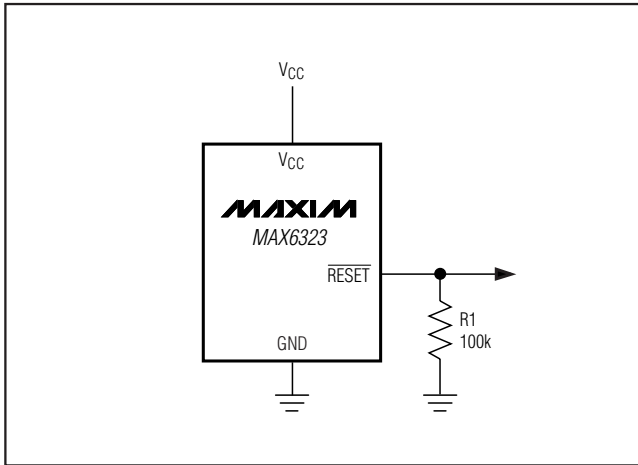

MAXIM

Figure 6. $\overline{RESET}$ Valid to V_{CC} = Ground Circuit

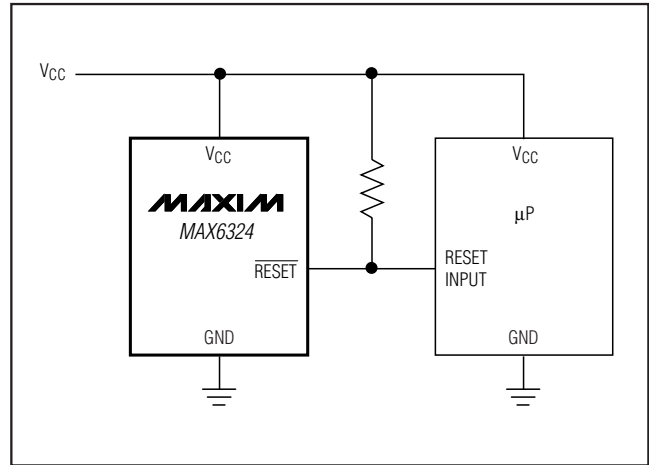

Figure 7. Interfacing to µPs with Bidirectional Reset Pins

Interfacing to µPs with Bidirectional Reset Pins

Since the $\overline{RESET}$ output on the MAX6324 is open-drain, this device easily interfaces with µPs that have bidirectional reset pins, such as the Motorola 68HC11. Connecting the µP supervisor's $\overline{RESET}$ output directly to the microcontroller's (µC's) $\overline{RESET}$ pin with a single pullup resistor allows either device to assert reset (Figure 7).

MAX6324 Open-Drain $\overline{RESET}$ Output Allows Use with Multiple Supplies

Generally, the pullup resistor connected to the MAX6324 will connect to the supply voltage that is being monitored at the IC's V_{CC} pin. However, some systems may use the open-drain output to level-shift from the monitored supply to reset circuitry powered by some other supply (Figure 8). Keep in mind that as the MAX6324's V_{CC} decreases below +1.2V, so does the IC's ability to sink current at $\overline{RESET}$. Also, with any pull-up resistor, $\overline{RESET}$ will be pulled high as V_{CC} decays toward 0. The voltage where this occurs depends on the pullup resistor value and the voltage to which it is connected.

Watchdog Software Considerations

To help the watchdog timer monitor software execution more closely, set and reset the watchdog input at different points in the program, rather than "pulsing" the watchdog input high-low-high or low-high-low. This technique avoids a "stuck" loop in which the watchdog

Figure 8. MAX6324 Open-Drain $\overline{RESET}$ Output Allows Use with Multiple Supplies

time would continue to be reset within the loop, keeping the watchdog from timing out.

Figure 9 shows an example of a flow diagram where the I/O driving the watchdog input is set high at the beginning of the program, set low at the beginning of every subroutine or loop, then set high again when the program returns to the beginning. If the program should "hang" in any subroutine, the problem would be quickly corrected, since the I/O is continually set low and the watchdog time is allowed to time out, causing a reset or interrupt to be issued.

MAX6323/MAX6324
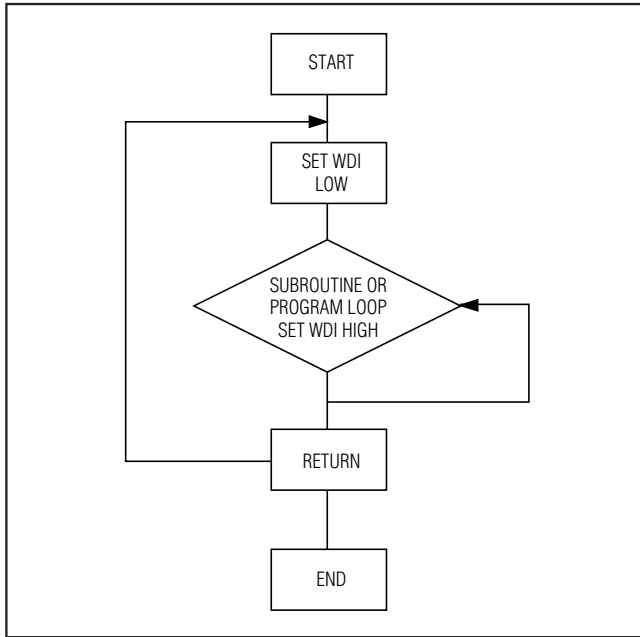

Figure 9. Watchdog Flow Diagram

$\overline{WDPO}$ to $\overline{MR}$ Loopback

An error detected by the watchdog often indicates that a problem has occurred in the µP code execution. This could be a stalled instruction or a loop from which the processor cannot free itself. If the µP will still respond to a nonmaskable input (NMI), the processor can be redirected to the proper code sequence by connecting the $\overline{WDPO}$ output to an NMI input. Internal RAM data should not be lost, but it may have been contaminated by the same error that caused the watchdog to time out.

If the processor will not recognize NMI inputs, or if the internal data is considered potentially corrupted when a watchdog error occurs, the processor should be restarted with a reset function. To obtain proper reset timing characteristics, the $\overline{WDPO}$ output should be connected to the $\overline{MR}$ input, and the $\overline{RESET}$ output should drive the µP $\overline{RESET}$ input (Figure 10). The short 1ms $\overline{WDPO}$ pulse output will assert the manual reset input and force the $\overline{RESET}$ output to assert for the full reset timeout period (100ms min). All internal RAM data is lost during the reset period, but the processor is guaranteed to begin in the proper operating state.
