

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

MAXIM

5V, Step-Down, Current-Mode PWM DC-DC Converters

General Description

The MAX730A/MAX738A/MAX744A are 5V-output CMOS, step-down switching regulators. The MAX738A/MAX744A accept inputs from 6V to 16V and deliver 750mA. The MAX744A guarantees 500mA load capability for inputs above 6V and has tighter oscillator frequency limits for low-noise (radio) applications. The MAX730A accepts inputs between 5.2V and 11V and delivers 450mA for inputs above 6V. Typical efficiencies are 85% to 96%. Quiescent supply current is 1.7mA and only 6µA in shutdown.

Pulse-width modulation (PWM) current-mode control provides precise output regulation and excellent transient responses. Output voltage accuracy is guaranteed to be $\pm 5\%$ over line, load, and temperature variations. Fixed-frequency switching allows easy filtering of output ripple and noise, as well as the use of small external components. These regulators require only a single inductor value to work in most applications, so no inductor design is necessary.

The MAX730A/MAX738A/MAX744A also feature cycle-by-cycle current limiting, overcurrent limiting, undervoltage lockout, and programmable soft-start protection.

Applications

- Portable Instruments
- Cellular Phones and Radios
- Personal Communicators
- Distributed Power Systems
- Computer Peripherals

Typical Operating Circuit

Features

- ♦ 750mA Load Currents (MAX738A/MAX744A)
- ♦ High-Frequency, Current-Mode PWM
- ♦ 159kHz to 212.5kHz Guaranteed Oscillator Frequency Limits (MAX744A)
- ♦ 85% to 96% Efficiencies
- ♦ 1.7mA Quiescent Current
- ♦ 6µA Shutdown Supply Current
- ♦ Single Preselected Inductor Value, No Component Design Required
- ♦ Overcurrent, Soft-Start, and Undervoltage Lockout Protection
- ♦ Cycle-by-Cycle Current Limiting
- ♦ 8-Pin DIP/SO Packages (MAX730A)

Ordering Information

Pin Description

PIN		NAME	FUNCTION
8-PIN DIP/SO	16-PIN WIDE SO		
1	2	$\overline{\text{SHDN}}$	Shutdown—active low. Ground to power-down chip, tie to V_+ for normal operation. Output voltage falls to 0V when $\overline{\text{SHDN}}$ is low.
2	3	REF	Reference-Voltage Output (+1.23V) supplies up to 100 μA for extended loads. Bypass to GND with a capacitor that does not exceed 0.047 μF .
3	7	SS	Soft-Start. Capacitor between SS and GND provides soft-start and short-circuit protection. 510k Ω resistor from SS to $\overline{\text{SHDN}}$ provides current boost.
4	8	CC	Compensation Capacitor Input externally compensates the outer feedback loop. Connect to OUT with a 330pF capacitor.
5	9	OUT	Output Voltage Sense Input provides regulation feedback sensing. Connect to +5V output.
6	10, 11	GND	Ground pins are internally connected. Connect both pins to ground.
7	12, 13, 14	LX	Drain of internal P-channel power MOSFET.
8	1, 15, 16	V_+	Supply-Voltage Input. Bypass to GND with 1 μF ceramic and large-value electrolytic capacitors in parallel. The 1 μF capacitor must be as close to V_+ and GND pins as possible.
	4, 5, 6	N.C.	No Connect—no internal connections to these pins.

5V, Step-Down, Current-Mode PWM DC-DC Converters

Detailed Description

The MAX730A/MAX738A/MAX744A switch-mode regulators use a current-mode pulse-width-modulation (PWM) control system coupled with a simple step-down (buck) regulator topography. They convert an unregulated DC voltage from 5.2V to 11V for the MAX730A, and from 6V to 16V for the MAX738A/MAX744A. The current-mode PWM architecture provides cycle-by-cycle current limiting, improved load-transient response characteristics, and simpler outer-loop design.

The controller consists of two feedback loops: an inner (current) loop that monitors the switch current via the current-sense resistor and amplifier, and an outer (voltage) loop that monitors the output voltage through the error amplifier (Figure 1). The inner loop performs cycle-by-cycle current limiting, truncating the power transistor on-time when the switch current reaches a predetermined threshold. This threshold is determined by the outer loop. For example, a sagging output voltage produces an error signal that raises the threshold, allowing the circuit to store and transfer more energy during each cycle.

Programmable Soft-Start

Figures 1 and 2 show a capacitor and a resistor connected to the soft-start (SS) pin to ensure an orderly power-up. Typical values are $0.1\mu\text{F}$ and $510\text{k}\Omega$. SS controls both the SS timing and the maximum output current that can be delivered while maintaining regulation.

The charging capacitor slowly raises the clamp on the error-amplifier output voltage, limiting surge currents at power-up by slowly increasing the cycle-by-cycle current-limit threshold. The $510\text{k}\Omega$ resistor sets the SS clamp at a value high enough to maintain regulation, even at currents exceeding 1A. This resistor is not necessary for lower-current loads. Refer to the Maximum Output Current vs. Supply Voltage graph in the *Typical Operating Characteristics*. Table 1 lists timing characteristics for selected capacitor values and circuit conditions.

The overcurrent comparator trips when the load exceeds approximately 1.5A. An SS cycle begins when either an undervoltage or overcurrent fault condition triggers an internal transistor to momentarily discharge the SS capacitor to ground. An SS cycle also begins at power-up and when coming out of shutdown mode.

Overcurrent Limiting

The overcurrent comparator triggers when the load current exceeds approximately 1.5A. On each clock cycle, the output FET turns on and attempts to deliver current until cycle-by-cycle or overcurrent limits are exceeded. Note that the SS capacitor must be greater than $0.01\mu\text{F}$

for overcurrent protection to function properly. A typical value is $0.1\mu\text{F}$.

Undervoltage Lockout

The MAX738A/MAX744A's undervoltage-lockout feature monitors the supply voltage at V_+ , and allows operation to start when V_+ rises above 5.7V (6V guaranteed). When V_+ falls, operation continues until the supply voltage falls below 5.45V (see the MAX738A/MAX744A Quiescent Supply Current vs. Supply Voltage graph in the *Typical Operating Characteristics*). The MAX730A is similar, starting operation at $V_+ > 4.7\text{V}$ and continuing to operate down to 4.45V. When an undervoltage condition is detected, control logic turns off the output power FET and discharges the SS capacitor to ground. This prevents partial turn-on of the power MOSFET and avoids excessive power dissipation. The control logic holds the output power FET off until the supply voltage rises above approximately 4.7V (MAX730A) or 5.7V (MAX738A/MAX744A), at which time an SS cycle begins.

Shutdown Mode

The MAX730A/MAX738A/MAX744A are shut down by keeping SHDN at ground. In shutdown mode, the output drops to 0V and the output power FET is held in an off state. The internal reference also turns off, which causes the SS capacitor to discharge. Typical standby current in shutdown mode is $6\mu\text{A}$. The actual design limit for standby current is much less than the $100\mu\text{A}$ specified in the *Electrical Characteristics* (see Standby Current vs. Temperature in the *Typical Operating Characteristics*). However, testing to tighter limits is prohibitive because the current takes several seconds to settle to a final value. For normal operation, connect SHDN to V_+ . Note that coming out of shutdown mode initiates an SS cycle.

Continuous-/Discontinuous-Conduction Modes

The input voltage, output voltage, load current, and inductor value determine whether the IC operates in continuous or discontinuous mode. As the inductor value or load current decreases, or the input voltage increases, the MAX730A/MAX738A/MAX744A tend to operate in discontinuous-conduction mode (DCM). In DCM, the inductor current slope is steep enough so it decays to zero before the end of the transistor off-time. In continuous-conduction mode (CCM), the inductor current never decays to zero, which is typically more efficient than DCM. CCM allows the MAX730A/MAX738A/MAX744A to deliver maximum load current, and is also slightly less noisy than DCM, because the peak-to-average inductor current ratio is reduced.

Internal Reference

The +1.23V bandgap reference supplies up to 100 μ A at REF. Connect a 0.01 μ F bypass capacitor from REF to GND.

Oscillator

The internal oscillator of the MAX730A typically operates at 170kHz (160kHz for the MAX738A and 185kHz for the MAX744A). The MAX744A is guaranteed to operate at a minimum of 159kHz and a maximum of 212.5kHz over the operating voltage and temperature range, making it ideal for use in portable communications systems. The *Typical Operating Characteristics* graphs indicate oscillator frequency stability over temperature and supply voltage.

Applications Information

Figure 3 shows the standard 5V step-down application circuits. Table 3 lists the components for the desired operating temperature range. These circuits are useful in systems that require high current at high efficiency and are powered by an unregulated supply, such as a battery or wall-plug AC-DC transformer. These circuits operate over the entire line, load, and temperature ranges using the single set of component values shown in Figure 3 and listed in Table 3.

Inductor Selection

The MAX730A/MAX738A/MAX744A require no inductor design because they are tested in-circuit, and are guaranteed to deliver the power specified in the Electrical Characteristics with high efficiency using a

MAX730A/MAX738A/MAX744A

5V, Step-Down, Current-Mode PWM DC-DC Converters

Figure 1. Detailed Block Diagram with External Components

single 100 μ H (MAX7_AC) or 33 μ H (MAX7_AE/AM) inductor. The inductor's incremental saturation current rating should be greater than 1A, and its DC resistance should be less than 0.8 Ω . Table 2 lists inductor types and suppliers for various applications. The surface-mount inductors have nearly equivalent efficiencies to the larger through-hole inductors.

Output Filter Capacitor Selection

The primary criterion for selecting the output filter capacitor is low equivalent series resistance (ESR). The product of the inductor current variation and the output capacitor's ESR determines the amplitude of the sawtooth ripple seen on the output voltage. Also, minimize the output filter capacitor's ESR to maintain AC stability. The capacitor's ESR should be less than 0.25 Ω to keep the output ripple less than 50mVp-p over the entire current range (using a 100 μ H inductor).

Capacitor ESR rises as the temperature falls, and excessive ESR is the most likely cause of trouble at temperatures below 0°C. Sanyo OS-CON series through-hole and surface-mount tantalum capacitors exhibit low ESR at temperatures below 0°C. Refer to Table 2 for recommended capacitor values and suggested capacitor suppliers.

Other Components

The catch diode should be a Schottky or high-speed silicon rectifier with a peak current rating of at least 1.5A for full-load (750mA) operation. The 1N5817 is a good choice. The 330pF outer-loop compensation capacitor provides the widest input voltage range and best transient characteristics. For low-current applications, the 510k Ω resistor may be omitted (see the Maximum Output Current vs. Supply Voltage graph (R₁ removed) in the *Typical Operating Characteristics*).

Printed Circuit Layouts

A good layout is essential for clean, stable operation. The layouts and component placement diagrams given in Figures 4, 5, 6, and 7 have been successfully tested over a wide range of operating conditions. Note that the 1 μ F bypass capacitor (C2) must be positioned as close to the V₊ and GND pins as possible. Also, place the output capacitor as close to the OUT and GND pins as possible. The traces connecting the input and output filter capacitors and the catch diode must be short to minimize inductance and capacitance. For this reason, avoid using sockets, and solder the IC directly to the PC board. Use an uninterrupted ground plane if possible.

Output-Ripple Filtering

A simple lowpass pi-filter (Figure 3) can be added to the output to reduce output ripple to about 5mVp-p. The cutoff frequency shown is 21kHz. Since the filter inductor is in series with the circuit output, its resistance should be minimized so the voltage drop across it is not excessive.
