Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

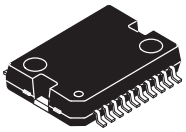
Quad Low-side Driver

33385

LOW-SIDE DRIVER

The MC33385 is a Quad Low-side Driver fully protected switch. This device is a general purpose Low-side Driver but has been especially designed to operate in engine management applications as injector driver or automotive gear box. It is interfaced directly with a microcontroller for parallel control of the load and the individual output diagnostic is done through a SPI. The diagnostic logic recognizes 4 failure types at each output stage: overcurrent, short to GND, open load, and over-temperature.



DH SUFFIX
VW SUFFIX (PB-FREE)
98ASH70702A
20-PIN HSOP

Features

- RDSON of 250mΩ per Output at 25°C
- Supplied from the main 5V V_{CC}
- Input CMOS Compatible
- Diagnostic through SPI
- Nominal Current of 2A per Output
- Current Limitation at 3A with Automatic Turn Off
- Output Internally Clamped at 50V typ for Inductive Load Drive
- Junction to Case Thermal Resistance of 4.4°C/W
- Individual Output over Temperature Shutdown
- Pb-Free Packaging Designated by Suffix Code VW

ELECTRICAL CHARACTERISTICS

MAXIMUM RATINGS

Table 2. Maximum Ratings

All voltages are with respect to ground unless otherwise noted. Exceeding these ratings may cause a malfunction or permanent damage to the device.

Ratings	Symbol	Value	Unit
ELECTRICAL RATINGS			
Voltage Range	Vcc	7.0	V
Continuous Output Voltage (With no reverse current)	V_{OUT}	45	V
Continuous Current	I_{OUTC}	2.5	A
Peak Output Current	I_{OUTP}	I_{SCBMAX}	A
Clamped Energy at the Switching OFF (See Figure 9)	W_{OFF}	70	mJ for 1ms
Input Voltage (Inputs)	V_{IN}	V_{CC} + 0.3	V
Input Protection Diode Current	I_{IN}	1.0	mA
Input Voltage (Outputs)	V_O	V_{CC} + 0.3	V
Input Protection Diode Current	I_O	1.0	mA
THERMAL RATINGS			
Operating Junction Temperature	T_J	150	°C
Thermal Resistance : Junction-case (One power stage in use)	R_{THJC}	4.5	kΩ
Thermal Resistance : Junction-ambient (Device soldered on printed circuit board)	R_{THJA}	50	kΩ
Peak Package Reflow Temperature During Reflow (1), (2)	T_{PPRT}	Note 2	°C

Notes

1. Pin soldering temperature limit is for 10 seconds maximum duration. Not designed for immersion soldering. Exceeding these limits may cause malfunction or permanent damage to the device.
2. Freescale's Package Reflow capability meets Pb-free requirements for JEDEC standard J-STD-020C. For Peak Package Reflow Temperature and Moisture Sensitivity Levels (MSL),
   Go to www.freescale.com, search by part number [e.g. remove prefixes/suffixes and enter the core ID to view all orderable parts. (i.e. MC33xxxD enter 33xxx), and review parametrics.

FUNCTIONAL DESCRIPTION

INTRODUCTION

The device is a Quad Low-side Driver driven by four CMOS input stages. Each output power transistor is protected against short to V_{BAT} by a zener clamp against overvoltage.

A diagnostic logic recognizes four failure types at the output stage : overcurrent, short to GND, open-load and overtemperature.

The failures are individually stored in a byte which can be read out via the serial interface (SPI).

OUTPUT STAGE CONTROL

Each of the four output stages is switched ON and OFF by an individual control line (NON-Input). The logic level of the control line is CMOS compatible. The output transistors are switched off when the inputs are not connected.

POWER TRANSISTORS

Each of the four output stages has its own zener clamp. This causes a voltage limitation at the power transistors when inductive loads are switched off. The drain voltage ramp occurring when output is switched on or off, is within defined limits. Output transistors can be connected in parallel to increase current capability. In this case, the associated inputs should be connected together.

SHORT-CIRCUIT AND OVERTEMPERATURE PROTECTION

If the output current increases above the short current limit for a time longer than t_{SCB} or if the temperature increases above T_{OFF} then the power transistor is immediately switched off. It remains switched off until the control signal on the NON-Input is switched off and on again.

DIAGNOSTICS

The following failures at the output stage are recognized :

Short -Circuit to V_{BAT} or overtemp = SCB (Highest priority)

Short -Circuit to GND..... = SCG

Open Load..... = OL (Lowest priority)

The SCB failure is recognized by an overcurrent (current above the short current limit) or an overtemperature.

If the current through the output stage is lower than the IOL-reference, after a filter time an OL failure will be recognized. This measurement is active while the power stage is switched on.

The SCG failure will recognize when the drain voltage is lower than the OL reference limit, while the output stage is switched off. All four outputs have an independent overtemperature detection and shutdown. All failures are stored in individual registers.

They can be read by the microprocessor via the serial interface. There is no failure detected if the power stage control time is shorter than the filter time.

DIAGNOSTIC INTERFACE

The communication between the microprocessor and the failure register runs via the SPI link. If there is a failure stored in the failure register, the first bit of the shift register is set to a high level. With the High/Low change on the NCS pin, the first bit of the diagnostic shift register will be transmitted to the SDO output. The SDO output is the serial output from the diagnostic shift register and it is put into a tri-state when the NCS pin is high. The CLK pin clocks the diagnostic shift register. New SDO data will appear on every rising edge of this pin and new SDI data will be latched on every CLK's falling edge into the shift register. With the first positive pulse of the CLK, the failure register will be cleared. There is no bus collision at a small spike at the NCS. The CLK is always LOW while the NCS-signal is changing.

RESET

There are two different reset functions realized :

Under voltage reset : as long as the V_{CC} voltage is lower than V_{CCRES}, the power stages are switched off and the failure-registers are reset.

Reset pin : as long as the NRES-pin is low, following circuits are reset :

- Power stages
- Failure register

UNDERVOLTAGE PROTECTION

At low V_{CC} voltage, the device remains switched off even if there is a voltage ramp at the OUT pin.
