

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## Super LDO™ Regulator Controller

### General Description

The MIC5156, MIC5157, and MIC5158 Super Low-Dropout (LDO) Regulator Controllers are single IC solutions for high-current low-dropout linear voltage regulation. Super LDO™ Regulators have the advantages of an external N-channel power MOSFET as the linear pass element.

The MIC5156/7/8 family features a dropout voltage as low as the  $R_{DS(ON)}$  of the external power MOSFET multiplied by the output current. The output current can be as high as the largest MOSFETs can provide.

The MIC5156/7/8 family operates from 3V to 36V. The MIC5156 requires an external gate drive supply to provide the higher voltage needed to drive the gate of the external MOSFET. The MIC5157 and MIC5158 each have an internal charge pump tripler to produce the gate drive voltage. The tripler is capable of providing enough voltage to drive a logic-level MOSFET to 3.3V output from a 3.5V supply and is clamped to 17.5V above the supply voltage. The tripler requires three external capacitors.

The regulator output is constant-current limited when the controller detects 35mV across an optional external sense resistor. An active-low open-collector flag indicates a low voltage of 8% or more below nominal output. A shutdown (low) signal to the TTL-compatible enable control reduces controller supply current to less than 1µA while forcing the output voltage to ground.

The MIC5156-3.3 and MIC5156-5.0 controllers have internally fixed output voltages. The MIC5156 [adjustable] output is configured using two external resistors. The MIC5157 is a fixed output controller which is externally configured to select

either 3.3V, 5.0V, or 12V. The MIC5158 can be configured as a fixed 5V controller or programmed to any voltage from 1.3V to 36V using two external resistors.

The MIC5156 is available in an 8-pin DIP or SOIC. The MIC5157 and MIC5158 are available in a 14-pin DIP or SOIC which operate from -40°C to +85°C.

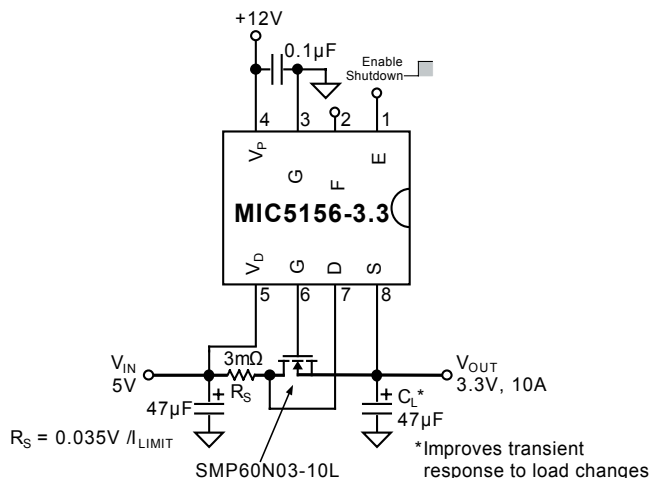

### Features

- 4.5mA typical operating current
- <1µA typical standby current
- Low external parts count
- Optional current limit (35mV typical threshold)
- 1% initial output voltage tolerance in most configurations
- 2% output voltage tolerance over temperature
- Fixed output voltages of 3.3V, 5.0V (MIC5156)
- Fixed output voltages of 3.3V, 5.0V, 12V (MIC5157)
- Programmable (1.3 to 36V) with 2 resistors (MIC5156/8)
- Internal charge pump voltage tripler (MIC5157/8)
- Enable pin to activate or shutdown the regulator
- Internal gate-to-source protective clamp
- All versions available in DIP and SOIC

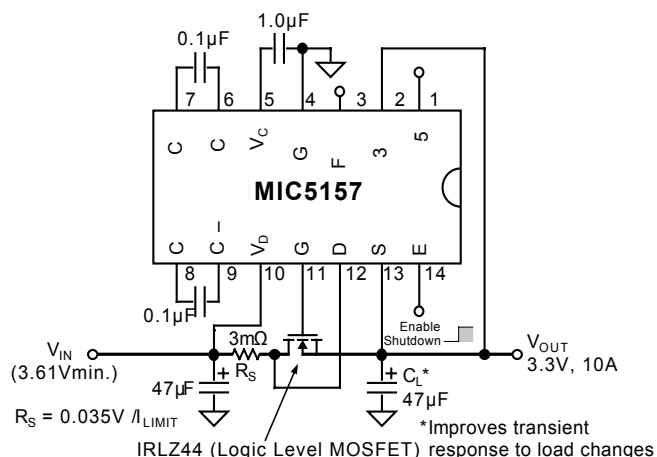

### Applications

- Ultrahigh current ultralow dropout voltage regulator
- Constant high-current source
- Low parts count 5.0V to 3.3V computer supply
- Low noise/low-dropout SMPS post regulator
- High-current, current-limited switch

### Typical Applications

10A 5V to 3.3V Desktop Computer Regulator

10A Low-Dropout Voltage Regulator

## Pin Configuration

**Pin Description MIC5156**

Pin Number	Pin Name	Pin Function
1	EN	Enable (Input): TTL high enables regulator; TTL low shuts down regulator.
2	FLAG	Output Flag (Output): Open collector output is active (low) when $V_{OUT}$ is more than 8% below nominal output. Circuit has 3% hysteresis.
3	GND	Circuit ground.
4	$V_P$	N-channel Gate Drive Supply Voltage: User supplied voltage for driving the gate of the external MOSFET.
5	$V_{DD}$	Supply Voltage (Input): Supply voltage connection. Connect sense resistor ( $R_S$ ) to $V_{DD}$ if current limiting used. Connect supply bypass capacitor to ground near device.
6	G	Gate (Output): Drives the gate of the external MOSFET.
7	D	Drain and Current Limit (Input): Connect to external MOSFET drain and external sense resistor (current limit), or connect to $V_{DD}$ and external MOSFET drain (no current limit).
8 (3.3V, 5V)	S	Source (Input): Top of internal resistive divider chain. Connect directly to the load for best load regulation.
8 (adjustable)	EA	Error Amplifier (Input): Connect to external resistive divider.

**Pin Description MIC5157, MIC5158**

Pin Number	Pin Name	Pin Function
1 (MIC5157)	5V	5V Configuration (Input): Connect to S (source) pin for 5V output.
1 (MIC5158)	EA	Error Amplifier (Input): Connect to external resistive divider to obtain adjustable output.
2 (MIC5157)	3.3V	3.3V Configuration (Input): Connect to S (source) pin for 3.3V output.
2 (MIC5158)	5VFB	5V Feedback (Input): Connect to EA for fixed 5V output.
3	FLAG	Output Voltage Flag (Output): Open collector is active (low) when $V_{OUT}$ is 8% or more below its nominal value.
4	GND	Circuit ground.
5	$V_{CP}$	Voltage Tripler Output [Filter Capacitor]. Connect a 1 to 10 $\mu$ F capacitor to ground.
6	C2-	Charge Pump Capacitor 2: Second stage of internal voltage tripler. Connect a 0.1 $\mu$ F capacitor from C2+ to C2-.
7	C2+	Charge Pump Capacitor 2: See C2- pin 6.
8	C1+	Charge Pump Capacitor 1: First stage of internal voltage tripler. Connect a 0.1 $\mu$ F capacitor from C1+ to C1-.
9	C1-	Charge Pump Capacitor 1: See C1+ pin 8.
10	$V_{DD}$	Supply Voltage (Input): Supply voltage connection. Connect sense resistor ( $R_S$ ) to $V_{DD}$ if current limiting used. Connect supply bypass capacitor to ground near device.
11	G	Gate (Output): Connect to External MOSFET gate.
12	D	Drain and Current Limit (Input): Connect to external MOSFET drain and external sense resistor (current limit), or connect to $V_{DD}$ and external MOSFET drain (no current limit).
13 (MIC5157)	S	Source and 3.3V/5V Configuration: Top of internal resistor chain. Connect to source of external MOSFET for 3.3V, 5V, and 12V operation. Also see 3.3V and 5V pin descriptions.
13 (MIC5158)	S	Source (Input): Top of internal resistor chain. Connect to top of external resistive divider and source of external MOSFET.
14	EN	Enable (Input): TTL high enables regulator; TTL low shuts down regulator.

**Absolute Maximum Ratings (Note 1)**

Supply Input ( $V_{DD}$ )	+38V
Enable Input ( $V_{EN}$ )	-0.3V to 36V
Gate Output ( $V_G$ ) MIC5156	+55V
Charge Pump Node ( $V_{CP}$ ) MIC5157/8	+55V
Source Connection ( $V_S$ )	1.3 to +36V
Flag ( $V_{FLAG}$ )	-0.3 to +40V
Storage Temperature ( $T_S$ )	-65°C to +150°C
Lead Temperature (soldering 10 sec.)	300°C

**Operating Ratings (Note 2)**

Ambient Temperature Range ( $T_A$ )	MIC515xBM/BN		-40°C to +85°C

## Functional Description

A *Super LDO Regulator* is a complete regulator built around Micrel's *Super LDO Regulator Controller*.

Refer to Block Diagrams MIC5156, MIC5157, and MIC5158.

### Version Differences

The MIC5156 requires an external voltage for MOSFET gate drive and is available in 3.3V fixed output, 5V fixed output, or adjustable output versions. With 8-pins, the MIC5156 is the smallest of the Super LDO Regulator Controllers.

The MIC5157 and MIC5158 each have an internal charge pump which provides MOSFET gate drive voltage. The MIC5157 has a selectable fixed output of 3.3V, 5V, or 12V. The MIC5158 may be configured for a fixed 5V or adjustable output.

### Enable (EN)

With at least 3.0V on  $V_{DD}$ , applying a TTL low to EN places the controller in shutdown mode. A TTL high on EN enables the internal bias circuit which powers all internal circuitry. EN must be pulled high if unused. The voltage applied to EN may be as high as 36V.

The controller draws less than 1 $\mu$ A in shutdown mode.

### Gate Enhancement

The Super LDO Regulator Controller manages the gate-

to-source enhancement voltage for an external N-channel MOSFET (regulator pass element) placed between the supply and the load. The gate-to-source voltage may vary from 1V to 16V depending upon the supply and load conditions.

Because the source voltage (output) approaches the drain voltage (input) when the regulator is in dropout and the MOSFET is fully enhanced, an additional higher supply voltage is required to produce the necessary gate-to-source enhancement. This higher gate drive voltage is provided by an external gate drive supply (MIC5156) or by an internal charge pump (MIC5157 and MIC5158).

### Gate Drive Supply Voltage (MIC5156 only)

The gate drive supply voltage must not be more than 14V above the supply voltage ( $V_P - V_{DD} < 14V$ ). The minimum necessary gate drive supply voltage is:

$$V_P = V_{OUT} + V_{GS} + 1$$

where:

$V_P$  = gate drive supply voltage

$V_{OUT}$  = regulator output voltage

$V_{GS}$  = gate-to-source voltage for full MOSFET gate enhancement

The error amplifier uses the gate drive supply voltage to drive the gate of the external MOSFET. The error amplifier output can swing to within 1V of  $V_P$ .

**Charge Pump (MIC5157/5158 only)**

The charge pump tripler creates a dc voltage across reservoir capacitor C3. External capacitors C1 and C2 provide the necessary storage for the stages of the charge pump tripler.

The tripler's approximate dc output voltage is:

$$V_{CP} \approx 3 (V_{DD} - 1)$$

where:

$$V_{CP} = \text{charge pump output voltage}$$

$$V_{DD} = \text{supply voltage}$$

The  $V_{CP}$  clamp circuit limits the charge pump voltage to 16V above  $V_{DD}$  by gating the charge pump oscillator ON or OFF as required. The charge pump oscillator operates at 160kHz.

The error amplifier uses the charge pump voltage to drive the gate of the external MOSFET. It provides a constant load of about 1mA to the charge pump. The error amplifier output can swing to within 1V of  $V_{CP}$ .

Although the MIC5157/8 is designed to provide gate drive using its internal charge pump, an external gate drive supply voltage can be applied to  $V_{CP}$ . When using an external gate drive supply,  $V_{CP}$  must not be forced more than 14V higher than  $V_{DD}$ .

When constant loads are driven, the ON/OFF switching of the charge pump may be evident on the output waveform. This is caused by the charge pump switching ON and rapidly increasing the supply voltage to the error amplifier. The period of this small charge pump excitation is determined by a number of factors: the input voltage, the 1mA op-amp load, any dc leakage associated with the MOSFET gate circuit, the size of the charge pump capacitors, the size of the charge pump reservoir capacitor, and the characteristics of the input voltage and load. The period is lengthened by increasing the charge pump reservoir capacitor (C3). The amplitude is reduced by weakening the charge pump—this is accomplished by reducing the size of the pump capacitors (C1 and C2). If this small burst is a problem in the application, use a 10 $\mu$ F reservoir capacitor at C3 and 0.01 $\mu$ F pump capacitors at C1 and C2.

Note that the recovery time to repetitive load transients may be affected with small pump capacitors.

**Gate-to-Source Clamp**

A gate-to-source protective voltage clamp of 16.6V protects the MOSFET in the event that the output voltage is suddenly forced to zero volts. This prevents damage to the external MOSFET during shorted load conditions. Refer to "Charge Pump" for normal clamp circuit operation.

The source connection required by the gate-to-source clamp is not available on the adjustable version of the MIC5156.

**Output Regulation**

At start-up, the error amplifier feedback voltage (EA), or internal feedback on fixed versions, is below nominal when compared to the internal 1.235V bandgap reference. This forces the error amplifier output high which turns on external MOSFET Q1. Once the output reaches regulation, the controller maintains constant output voltage under changing input and load conditions by adjusting the error amplifier output voltage (gate enhancement voltage) according to the feedback voltage.

**Out-of-Regulation Detection**

When the output voltage is 8% or more below nominal, the open-collector FLAG output (normally high) is forced low to signal a fault condition. The FLAG output can be used to signal or control external circuitry. The FLAG output can also be used to shut down the regulator using the EN control.

**Current Limiting**

Super LDO Regulators perform constant-current limiting (not foldback). To implement current limiting, a sense resistor ( $R_S$ ) must be placed in the "power" path between  $V_{DD}$  and D (drain).

If the voltage drop across the sense resistor reaches 35mV, the current limit comparator reduces the error amplifier output. The error amplifier output is decreased only enough to reduce the output current, keeping the voltage across the sense resistor from exceeding 35mV.

**Application Information****MOSFET Selection**

Standard N-channel enhancement-mode MOSFETs are acceptable for most Super LDO regulator applications.

Logic-level N-channel enhancement-mode MOSFETs may be necessary if the external gate drive voltage is too low (MIC5156), or the input voltage is too low, to provide adequate charge pump voltage (MIC5157/8) to enhance a standard MOSFET.

**Circuit Layout**

For the best voltage regulation, place the source, ground, and error amplifier connections as close as possible to the load. See figures (1a) and (1b).

**Figure 1a. Connections for Fixed Output**

Figure 1b. Connections for Adjustable Output

\* Optional 16V zener diode recommended in applications where  $V_G$  is greater than 18V

Figure 1c. MIC5156 Connections for Adjustable Output

### MOSFET Gate-to-Source Protection

When using the adjustable version of the MIC5156, an external 16V zener diode placed from gate-to-source is recommended for MOSFET protection. All other versions of the Super LDO regulator controller use the internal gate-to-source clamp.

### Output Voltage Configuration

#### Fixed Configurations

The MIC5156-3.3 and MIC5156-5.0 are preset for 3.3V and 5.0V respectively.

The MIC5157 operates at 3.3V when the 3.3V pin is connected to the S (source) pin; 5.0V when the 5.0V pin is connected to the S pin; or 12V if the 3.3V and 5.0V pins are open.

The MIC5158 operates at a fixed 5V (without an external resistive divider) if the 5VFB pin is connected to EA.

### Adjustable Configurations

Micrel's MIC5156 [adjustable] and MIC5158 require an external resistive divider to set the output voltage from 1.235V to 36V. For best results, use a 10kΩ resistor for R2. See equation (1) and figure (2).

$$1) \quad R_1 = 1 \times 10^4 \left( \frac{V_{OUT}}{1.235} - 1 \right)$$

Figure 2. Typical Resistive Divider

### Input Filter Capacitor

The Super LDO requires an input bypass capacitor for accommodating wide changes in load current and for decoupling the error amplifier and charge pump. A medium to large value low-ESR (equivalent series resistance) capacitor is best, mounted close to the device.

### Output Filter Capacitor

An output filter capacitor may be used to reduce ripple and improve load regulation. Stable operation does not require a large capacitor, but for transient load regulation the size of the output capacitor may become a consideration. Common aluminum electrolytic capacitors perform nicely; very low-ESR capacitors are not necessary. Increased capacitance (rather than reduced ESR) is preferred. The capacitor value should be large enough to provide sufficient  $I = C \times dV/dt$  current consistent with the required transient load regulation quality. For a given step increase in load current, the output voltage will drop by about  $dV = I \times dt/C$ , where  $I$  represents the increase in load current over time  $t$ . This relationship assumes that all output current was being supplied via the MOSFET pass device prior to the load increase. Small (0.01μF to 10μF) film capacitors parallel to the load will further improve response to transient loads.

Some linear regulators specify a minimum required output filter capacitance because the capacitor determines the dominant pole of the system, and thereby stabilizes the system. This is not the situation for the MIC5156/7/8; its dominant pole is determined within its error amplifier.

**Current Limiting**

Current sensing requires a low-value series resistance ( $R_S$ ) between  $V_{DD}$  and D (drain). Refer to the typical applications. The internal current-limiting circuit limits the voltage drop across the sense resistor to 35mV. Equation (2) provides the sense resistor value required for a given maximum current.

$$2) \quad R_S = \frac{35mV}{I_{LIM}}$$

where:

- $R_S$  = sense resistor value
- $I_{LIM}$  = maximum output current

Most current-limited applications require low-value resistors. See *Application Hints 21 and 25* for construction hints.

**Non-Current-Limited Applications**

For circuits not requiring current limiting, do not use a sense resistor between  $V_{DD}$  and D (drain). See figure (3). The controller will not limit current when it does not detect a 35mV drop from  $V_{DD}$  to D.

**Figure 3. No Current Limit**

**3.3V Microprocessor Applications**

For computer designs that use 3.3V microprocessors with 5V logic, the FLAG output can be used to suppress the 5V supply until the 3.3V output is in regulation. Refer to the external components shown with the MIC5156 Block Diagram.

**SMPS Post Regulator Application**

A Super LDO regulator can be used as a post regulator for a switch-mode power supply. The Super LDO regulator can provide a significant reduction in peak-to-peak ripple voltage.

**High-Current Switch Application**

All versions of the MIC5156/7/8 may be used for current-limited, high-current, high-side switching with or without voltage regulation. See figure (4a). Simply leave the “S” terminal open. A 16V zener diode from the gate to the source of the MOSFET protects the MOSFET from overdrive during fault conditions.

**Figure 4a. High-Side Switch**

If a MIC5157 or MIC5158 is used and is shutdown for a given time, the charge pump reservoir  $V_{CP}$  will bleed off. If recharging the reservoir causes an unacceptable delay in the load reaching its operating voltage, do not use the EN pin for on/off control. Instead, use the MIC5158, hold EN high to keep the charge pump in continuous operation, and switch the MOSFET on or off by overriding the error amplifier input as shown in figure (4b).

**Figure 4b. Fast High-Side Switch**

**Battery Charger Application**

The MIC5158 may be used in constant-current applications such as battery chargers. See figure (5). The regulator supplies a constant-current ( $35mV \div R3$ ) until the battery approaches the float voltage:

$$V_{FL} = 1.235 \left( 1 + \frac{R1}{R2} \right)$$

where:

$$V_{FL} = \text{float voltage}$$

At float voltage, the MOSFET is shut off. A trickle charge is supplied by R4.

Figure 5. Battery Charger Concept

### Uninterruptible Power Supply

The MIC5157 and two N-channel MOSFETs provide battery switching for uninterruptible power as shown in figure (6). Two MOSFETs are placed source-to-source to prevent current flow through their body diodes when switched off. The Super LDO regulator is continuously enabled to achieve fast battery switch-in. Careful attention must be paid to the ac-line monitoring circuitry to ensure that the output voltage does not fall below design limits while the battery is being switched in.
