## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## MICRF219

## NOT RECOMMENDED <br> REFER TO MICRF219A FOR NEW DESIGNS

## General Description

The MICRF219 is a 300 MHz to 450 MHz superheterodyne, image-reject, RF receiver with Automatic Gain Control, OOK/ASK demodulator and analog RSSI output. The device integrates Auto-Poll, Valid Bit-Check, Squelch, and Desense features. It only requires a crystal and a minimum number of external components to implement. It is ideal for low-cost, low-power, RKE, TPMS, and remote actuation applications.
The MICRF219 achieves -110 dBm sensitivity at a data rate of 1 kbps (Manchester encoded). Four demodulator filter bandwidths are selectable in binary steps from 1625 Hz to 13 kHz at 433 MHz , allowing the device to support data rates to 10 kbps . The device operates from a supply voltage of 3.0 V to 3.6 V , and consumes 4.0 mA of supply current at 315 MHz and 6.0 mA at 433.92 MHz . A shutdown mode reduces supply current to 0.5 uA . The Auto-Polling feature allows the MICRF219 to sleep and poll for user defined periods, thus further reducing supply current. The Valid Bit-Check feature, when enabled in Auto-Poll mode, fully awakes the receiver and sends bits to the microcontroller once a valid number of bits are detected. During normal operation an optional Squelch feature disables the data output until valid bits are detected. An optional Desense feature reduces gain by 6 dB to 42 dB , distancing the receiver from distantly placed, undesired transmitters.

## Features

- -110 dBm sensitivity at 1 kbps with $1 \%$ BER
- Supports data rates up to 10 kbps at 433.92 MHz
- 25 dB Image-Reject Mixer
- No IF Filter Required
- 60dB Analog RSSI Output
- 3.0 V to 3.6 V Supply Voltage Range
- 4.0 mA supply current at 315 MHz (continuous receive)
- 6.0 mA supply current at 434 MHz (continuous receive)
- $0.5 u A$ supply current in Shutdown Mode
- Optional Auto-Polling (sleep mode, current $<0.1 \mathrm{~mA}$ )
- Optional Valid Bit-Check in Auto-Poll Mode
- Optional Programmable 6dB to 42dB Desense
- Optional Data Output Squelch until valid bits detected
- 16-pin QSOP Package ( $4.9 \mathrm{~mm} \times 6.0 \mathrm{~mm}$ )
- $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ Temperature Range
- 2kV HBM ESD Rating
- Evaluation board QR219BPF Available

## Ordering Information

| Part Number | Temperature Range | Package |
| :--- | :---: | :---: |
| MICRF219AYQS | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ | $16-$ Pin QSOP |

## Typical Application

QwikRadio is a registered trademark of Micrel, Inc.
Micrel Inc. • 2180 Fortune Drive•San Jose, CA 95131•USA•tel +1 (408) 944-0800• fax + 1 (408) 474-1000• http://www.micrel.com

## Pin Configuration

## Pin Description

| $\begin{aligned} & \text { 16-Pin } \\ & \text { QSOP } \end{aligned}$ | Pin Name | Pin Function |
| :---: | :---: | :---: |
| 1 | RO1 | Reference Oscillator Input: Reference resonator input connection to pierce oscillator stage. May also be driven by external reference signal of 200 mVp -p to 1.5 V p-p amplitude maximum. Internal capacitance of 7 pF to GND during normal operation. |
| 2 | GNDRF | Negative supply connection associated with ANT RF input. |
| 3 | ANT | Antenna Input: RF signal input from antenna. Internally AC coupled. It is recommended a matching network with an inductor-to-RF ground be used to improve ESD protection. |
| 4 | GNDRF | Ground connection for ANT RF input. |
| 5 | VDD | Positive supply connection for all chip functions. Bypass with $0.1 \mu \mathrm{~F}$ capacitor located as close to the VDD pin as possible. |
| 6 | SQ | Squelch Control Logic-Level Input. An internal pull-up pulls the logic-input HIGH when the device is enabled. Bit D17 sets whether squelch is enabled or disabled when a logic-level signal is applied the SQ pin. See Squelch Enable Truth-Table on page |
| 7 | SELO | Demodulator Filter Bandwidth Select Logic-Level Input. Internal pull-up (3uA typical) when not in shutdown or SLEEP mode. Used in conjunction with SEL1 to control D3 bandwidth LSB when serial interface contains default setting. It does not need to be defined in SLEEP mode. |
| 8 | SHDN | Shutdown control Logic-Level Input. A logic-level LOW enables the device. A logic-level HIGH places the device in low-power shutdown mode. An internal pull-up pulls the logic input HIGH. |
| 9 | GND | Negative supply connection for all chip functions except for RF input. |
| 10 | DO | Data Input and Output. Demodulated data output. May be blanked until bit checking test is acceptable. A current limited CMOS output during normal operation this pin is also used as a CMOS Schmitt input for serial interface data. A $25 \mathrm{k} \Omega$ pull-down is present when device is in shutdown and sleep modes. |
| 11 | SEL1 | Demodulator Filter Bandwidth Select Logic-Level Input: Internal (3uA typical) pull-up when not in shutdown or SLEEP mode. Used in conjunction with SELO, to control D4 bandwidth MSB, when serial interface contains default setting. It does not need to be defined in SLEEP mode. |
| 12 | CTH | Demodulation threshold voltage integration capacitor. Capacitor-to-GND sets the settling time for the demodulation data slicing level. Values above 1 nF are recommended and should be optimized for data rate and data profile. |
| 13 | CAGC | AGC filter capacitor. A capacitor, normally greater than $0.47 \mu \mathrm{~F}$, is connected from this pin-to-GND |
| 14 | RSSI | Received signal strength indication (output): Output is from a switched capacitor integrating op amp with $220 \Omega$ typical output impedance. |
| 15 | SCLK | Serial interface input clock. CMOS Schmitt input. A $25 \mathrm{k} \Omega$ pull-down is present when device is in shutdown mode. |
| 16 | RO2 | Reference resonator connection. Internal capacitance of 7 pF to GND during normal operation. |

## Absolute Maximum Ratings ${ }^{(1)}$

## Operating Ratings ${ }^{(2)}$

Supply voltage (VDD)............................+3.0V to +3.6 V
Ambient Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$................. $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$
Input Voltage (Vin)
3.6 V

Maximum Input RF Power...............................-20dBm
Receive Modulation Duty Cycle ${ }^{(6)}$.................... 20~80\%
Frequency Range..........................300MHz to 450 MHz

## Electrical Characteristics

Specifications apply for $\mathrm{V}_{\mathrm{DD}}=3.3 \mathrm{~V}$, $\mathrm{GND}=0 \mathrm{~V}, \mathrm{C}_{\mathrm{AGC}}=4.7 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{TH}}=0.1 \mu \mathrm{~F}, \mathrm{f}_{\mathrm{RX}}=433.92 \mathrm{MHz}$ unless otherwise noted. | RSSI Response Time | 50\% data duty cycle, input power to Antenna = 20 dBm |  | 0.3 |  | sec |

## Notes:

1. Exceeding the absolute maximum rating may damage the device.
2. The device is not guaranteed to function outside of its operating rating.
3. Device is ESD sensitive. Use appropriate ESD precautions. Exceeding the absolute maximum rating may damage the device.
4. Sensitivity is defined as the average signal level measured at the input necessary to achieve $10^{-2} \mathrm{BER}$ (bit error rate). The input signal is defined as a return-to-zero (RZ) waveform with $50 \%$ average duty cycle (Manchester encoded) at a data rate of 1 kbps .
5. When data burst does not contain preamble, duty cycle is defined as total duty cycle, including any "quiet" time between data bursts. When data bursts contain preamble sufficient to charge the slice level on capacitor $\mathrm{C}_{\boldsymbol{T} \boldsymbol{H}}$, then duty cycle is the effective duty cycle of the burst alone. [For example, 100 msec burst with $50 \%$ duty cycle, and 100 msec "quiet" time between bursts. If burst includes preamble, duty cycle is $\mathrm{T}_{\text {ON }} /\left(\mathrm{T}_{\text {ON }}+\mathrm{t}_{\text {off }}\right)=50 \%$; without preamble, duty cycle is $\mathrm{T}_{\text {ON }} /\left(\mathrm{T}_{\text {ON }}+\mathrm{T}_{\text {OFF }}+\mathrm{T}_{\text {QUEET }}\right)=50 \mathrm{msec} /(200 \mathrm{msec})=25 \%$. $\mathrm{T}_{\text {ON }}$ is the (Average number of 1 's/burst) $\times$ bit time, and $T_{\text {OFF }}=\left(T_{\text {BURST }}-T_{\text {ON }}.\right)$

## Typical Characteristics

## Functional Diagram

Figure 1. Simplified Block Diagram

## Functional Description

The simplified block diagram, shown in Figure 1, illustrates the basic structure of the MICRF219 receiver. It is made up of four sub-blocks:

- UHF Down-converter
- OOK Demodulator
- Reference and Control logic
- Auto-poll circuitry

Outside the device, the MICRF219 receiver requires just three components to operate: two capacitors (CTH, and CAGC) and the reference frequency device (usually a quartz crystal). An additional five components are used to improve performance; a power supply decoupling capacitor, two components for the matching network, and two components for the pre-selector band-pass filter.

## Receiver Operation

## UHF Downconverter

The UHF down-converter has six components: LNA, mixers, synthesizer, image reject filter, band pass filter and IF amp.

## LNA

The RF input signal is AC-coupled into the gate circuit of the grounded source LNA input stage. The LNA is a Cascoded NMOS amplifier. The amplified RF signal is then fed to the RF ports of two double balanced mixers.

## Mixers and Synthesizer

The LO ports of the Mixers are driven by quadrature local oscillator outputs from the synthesizer block. The local oscillator signal from the synthesizer is placed on the low side of the desired RF signal to allow suppression of the image frequency at twice the IF frequency below the wanted signal. The local oscillator is set to 32 times the crystal reference frequency via a phase-locked loop synthesizer with a fully integrated loop filter.

## Image-Reject Filter and Band-Pass Filter

The IF ports of the mixer produce quadrature-down converted IF signals. These IF signals are low-pass filtered to remove higher frequency products prior to the image reject filter where they are combined to reject the image frequencies. The IF signal then passes through a third order band pass filter. The IF center frequency is 1.2 MHz . The IF BW is 330 kHz @ 433.92 MHz . This varies with RF operating frequency.

The IF BW can be calculated via direct scaling:

$$
\begin{aligned}
& \mathrm{BW}_{\mathrm{IF}}=\mathrm{BW}_{\mathrm{IF} @ 433.92 \mathrm{MHz}} \times \\
& \left(\frac{\text { Operating Freq }(\mathrm{MHz})}{433.92}\right)
\end{aligned}
$$

These filters are fully integrated inside the MICRF219.
After filtering, four active gain controlled amplifier stages enhance the IF signal to its proper level for demodulation.

## OOK Demodulator

The demodulator section is comprised of detector, programmable low pass filter, slicer, and AGC comparator.

## Detector and Programmable Low-Pass Filter

The demodulation starts with the detector removing the carrier from the IF signal. Post detection, the signal becomes base band information. The programmable low-pass filter further enhances the baseband information. There are four programmable low-pass filter BW settings: $1625 \mathrm{~Hz}, 3250 \mathrm{~Hz}, 6500 \mathrm{~Hz}, 13000 \mathrm{~Hz}$ for 433.92 MHz operation. Low pass filter BW will vary with RF Operating Frequency. Filter BW values can be easily calculated by direct scaling. See equation below for filter BW calculation:
$\mathrm{BW}_{\text {Operating Freq }}=\mathrm{BW}_{@ 433.92 \mathrm{MHz}^{*}}\left(\frac{\text { Operating Freq }(\mathrm{MHz})}{433.92}\right)$

It is very important to choose filter setting that fits best the intended data rate to minimize data distortion.
Demod BW is set at $13000 \mathrm{~Hz} @ 433.92 \mathrm{MHz}$ as default (assuming both SEL0 and SEL1 pins are floating). The low pass filter can be hardware set by external pins SEL0 and SEL1.

| SEL0 | SEL1 | Demod BW (@ 434MHz) |
| :---: | :---: | :--- |
| 0 | 0 | 1625 Hz |
| 1 | 0 | 3250 Hz |
| 0 | 1 | 6500 Hz |
| 1 | 1 | $13000 \mathrm{~Hz} \quad$ - default |

Table 1. Demodulation BW Selection

## Slicer and Slicing Level

The signal, prior to the slicer, is still AM. The data slicer converts the AM signal into ones and zeros based on the threshold voltage built up in the CTH capacitor. After the slicer, the signal is ASK or OOK digital data.
The slicing threshold is default at $50 \%$. The slicing threshold can be set via serial programming through register D5 and D6.

| D5 | D6 | Slicing Level |
| :---: | :---: | :--- |
| 1 | 0 | Slice Level 30\% |
| 0 | 1 | Slice Level $40 \%$ |
| 1 | 1 | Slice Level $50 \% \quad$ - default |
| 0 | 0 | Slice Level $60 \%$ |

## AGC Comparator

The AGC comparator monitors the signal amplitude from the output of the programmable low-pass filter. When the output signal is less than 750 mV thresh-hold, $1.5 \mu \mathrm{~A}$ current is sourced into the external CAGC capacitor. When the output signal is greater than 750 mV , a $15 \mu \mathrm{~A}$ current sink discharges the CAGC capacitor. The voltage developed on the CAGC capacitor acts to adjust the gain of the mixer and the IF amplifier to compensate for RF input signal level variation.

## Desense

Desense is a function designed to reduce the sensitivity of the MICRF219 receiver to a maximum of 45 dB for training the MICRF219 receiver. This is done in order to recognize an intended transmitter. Very often, a receiver needs to learn how to recognize a particular transmitter. It is important for the receiver not to learn the signal of a stray transmitter near by. The simplest solution is to turn down the receiver gain, so the receiver only recognizes the transmitter at close range.

The de-sense function is accessible only through serial programming.

| D0 | D1 | D2 | MODE: Desense |
| :---: | :---: | :---: | :--- |
| 0 | X | X | No Desense - default |
| 1 | 0 | 0 | 6dB Desense |
| 1 | 1 | 0 | 16dB Desense |
| 1 | 0 | 1 | 30dB Desense |
| 1 | 1 | 1 | 42dB Desense |

## Reference Control

There are 2 components in Reference and Control subblock: 1) Reference Oscillator and 2) Control Logic through parallel Inputs: SELO, SEL1, SHDN

## Reference Oscillator

The reference oscillator in the MICRF219 (Figure 2) uses a basic Pierce crystal oscillator configuration with MOS transconductor to provide negative resistance. Though the MICRF219 has build-in load capacitors for the crystal oscillator, the external load capacitors are still required for tuning it to the right frequency. R01 and R02 are external pins of the MICRF219 to connect the crystal to the reference oscillator.
Reference oscillator crystal frequency can be calculated:

$$
F_{\text {REF OSC }}=F_{\text {RF }} /(32+1.1 / 12)
$$

For $433.92 \mathrm{MHz}, \mathrm{F}_{\text {Ref osc }}=13.52127 \mathrm{MHz}$.
To operate the MICRF219 with minimum offset, crystal frequencies should be specified with 10 pF loading capacitance.

Figure 2. Reference Oscillator Circuit

Figure 3. Autopoll, Bit-Check Block Diagram

## Auto-Polling

The auto-poll block (Figure 3) contains a low power oscillator that drives the sleep timer when the rest of the device is powered down. It also contains circuits to check whether the received bits are good. Autopolling is controlled by bit D15 in the serial register, in conjunction with bits D12, D13, D14 to set the sleep timer period. Bits D7, D8, are used for control of the bit-check operation and bits D9, D10, D11 are used to adjust the sensitivity of the bit-check action.

## Auto-Polling without Bit-Checking

For simple auto-polling without bit-checking, send a serial command with bit D15 set high and bits D12, D13, D14 set to the desired sleep time. The device will go to sleep for the programmed timer duration then wake up to receive data if it is present. The device will stay awake until serial bit D15 is set low, then set high again, to enable a further sleep period. The sleep duty cycle may be controlled by the timing of serial commands.

## Auto-Polling with Bit-Checking

For auto-polling with bit-checking, the serial register bits D7and D8 need to be set for the number of bits to be checked as good, before the receiver outputs data at the DO pin. The bit-check window bits D9, D10, D11 must also be set to match the data period. The shortest default window time gives the least critical bit check action. For better discrimination, the window setting may be increased up towards the normal minimum time expected between data edges. Note
that a window time set longer than this will result in all bits being tested as bad and the device will remain in sleep polling mode. Now, when the serial command sets bit D15 high, the device will go to sleep for the timer period and will then awake to receive and check bits. The device will output data again at DO as soon as the programmed numbers of good RTZ bits have been received. If a bad bit is seen, the device will return to sleep mode and poll again for good bits after the sleep period. Both high and low periods are checked for each RTZ bit. The device will continue to check bits until sufficient good bits enable the device to wake up, or bad bits return the device to sleep.

## Operation

Received pulse edges trigger a programmable window timer clocked by the reference frequency. If the next pulse edge falls within this window the bit is flagged as bad. Detected good bits are counted and the device will wake up once sufficient pulses have been received. Two bad pulses or a lack of pulses will cause the device to go to sleep for a further sleep timeout period.

## Squelch

During normal operation, if four or less out of eight bit pulses are good, the DO output is squelched. If good bit count increases to seven or more in any eight sequential bits, squelch is disabled allowing data to output at DO pin.

## Serial Interface Register Programming

## Application Information

Figure 4. QR219BPF Application Example, 433.92MHz

## Antenna and RF Port Connections

Figure 4 shows the schematic of the QR219BPF configured for 433.29 MHz operation. Figure 19 through Figure 23 are PCB pictures. The QR219BPF is a good starting point for the prototyping of most applications. Current design offers two antenna options: A wire antenna or $50 \Omega$ SMA antenna. The SMA connection also allows an RF signal to be injected for test or verification. To use an antenna such as a $50 \Omega$ whip, remove the SMA and solder the whip antenna in the hole on the PCB instead. A wire of 22AWG with 167 mm ( 6 .-inch) can be used as a substitution if low cost antenna is needed.

## Front-End Band Pass Filter

Components L1 and C8 form the band-pass filter at front of the receiver. Its purpose is to attenuate undesired outside band noise that degrades the receiver performance. It is calculated by the parallel resonance equation:

Table 2 shows the component values for most often used frequencies.

| Freq (MHz) | C8 (pF) | L1 (nH) |
| :---: | :---: | :---: |
| 315.0 | 6.8 | 39 |
| 390.0 | 6.8 | 24 |
| 418.0 | 6.0 | 24 |
| 433.92 | 5.6 | 24 |

## Table 2. Front Band-Pass Filter values for Various Frequencies

This band-pass filter can be removed if the outside band noise does not cause a problem. The MICRF219 has built-in image reject mixers which improve the selectivity significantly and reject outside band noise.

$$
f=1 /(2 \times P l \times(S Q R T L 1 \times C 8))
$$

## Low-Noise Amplifier Input Matching

Capacitor C3 and inductor L2 form the " L " shape input matching network. The capacitor provides additional attenuation for low-frequency outside band noise. The inductor provides additional ESD protection for the antenna pin. Two methods can be used to find these values that best matched near $50 \Omega$. One method is done by calculating the values using the equations below and the other is using a Smith chart utility. The latter is made easier via a software plot where components are added on. In this way, the user can see the impedance moving direction for best values of C8 and L1 toward to central matching point, like WinSmith by Noble Publishing.

To calculate the matching values, one needs to know the input impedance of the device. Table 3 shows the input impedance of the MICRF219 and suggested matching values for the most often used frequencies. These suggested values may be different if the layout is not exactly the same as the one made here:

| Freq (MHz) | C3 (pF) | L2(nH) | Z device ( $\mathbf{\Omega})$ |
| :---: | :---: | :---: | :---: |
| 315 | 1.8 | 68 | $33-\mathrm{j} 235$ |
| 390 | 1.5 | 47 | $23-\mathrm{j} 199$ |
| 418 | 1.5 | 43 | $21-\mathrm{j} 186$ |
| 433.92 | 1.5 | 39 | $19-\mathrm{j} 174$ |

Table 3. Matching Values for the Most Used Frequencies

For the frequency of 433.92 MHz , the input impedance is $Z=18.6-j 174.2 \Omega$, then the matching components are calculated by:
Equivalent parallel $=B=1 / Z=0.606+j 5.68 \mathrm{msiemens}$
$\operatorname{Rp}=1 / \operatorname{Re}(B) ; X p=1 / \operatorname{lm}(B)$
$R p=1.65 \mathrm{k} \Omega ; \quad X p=176.2 \Omega$
Q = SQRT (Rp/50 + 1)
$\mathrm{Q}=5.831$
$X m=R p / Q$
$X m=282.98 \Omega$
Resonance Method for L-shape Matching Network
Lc = Xp / ( $2 \times$ Pi×f);
Lp $=\mathrm{Xm} /(2 \times$ Pixf $)$
$\mathrm{L} 2=(\mathrm{Lc} \times \mathrm{Lp}) /(\mathrm{Lc}+\mathrm{Lp}) ; \quad \mathrm{C} 3=1 /(2 \times \mathrm{Pi} \times f \times \mathrm{Xm})$
$\mathrm{L} 2=39.8 \mathrm{nH}$
C3 $=1.3 \mathrm{pF}$

Doing the same calculation example with the Smith Chart, would appear as follows,
First, one plots the input impedance of the device, ( $Z=18.6$ - j174.2) $\Omega$ @ 433.92MHz.(Figure 5):

Figure 5. Device's Input Impedance, $Z=19-j 174 \Omega$

Second, one plots the shunt inductor ( 39 nH ) and the series capacitor (1.5pF) for the desired input impedance (Figure 6). One can then see the matching leading to the center of the Smith Chart or close to $50 \Omega$.

Figure 6. Plotting of Shunt Inductor and Series Capacitor

## Crystal Selection

Crystal Y1 or Y1A (SMT or leaded respectively) is the reference clock for all the device internal circuits.
Crystal characteristics of 10 pF load capacitance, 30 ppm , ESR $<50 \Omega,-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ temperature range are desired. Table 4 shows Micrel's approved crystal suppliers such as (www.hib.com.br or http://www.abracon.com/ ) and the frequencies.
The oscillator of the MICRF219 is a Pierce-type oscillator. Good care must be taken when laying out the printed circuit board. Avoid long traces and place the ground plane on the top layer close to the REFOSC pins RO1 and RO2. When care is not taken in the layout, and the crystals used are not verified, the oscillator may take longer time to start. Time-to-good-data in the DO pin will be longer as well. In some cases, if the stray capacitance is too high (> 20 pF ). In this case, either the receiving central frequency will offset too much or the oscillator may not start.
The crystal frequency is calculated by REFOSC = RF Carrier/(32+(1.1/12)). The local oscillator is low-side injection ( $32 \times 13.52127 \mathrm{MHz}=432.68 \mathrm{MHz}$ ), that is, its frequency is below the RF carrier frequency and the image frequency is below the LO frequency. See Figure 7. The product of the incoming RF signal and local oscillator signal will yield the IF frequency, which will be demodulated by the detector of the device.

Figure 7. Low-Side Injection Local Oscillator

| REFOSC (MHz) | Carrier (MHz) | HIB Part Number | Abracon Part Number |
| :--- | :--- | :--- | :--- |

Table 4. Crystal Frequencies and Vendor Part Numbers

## Demodulator Bandwidth Selection and Data Stream Optimization

JP1 and JP2 are the bandwidth selection for the demodulator bandwidth. To set it correctly, it is necessary to know the shortest pulse width of the encoded data sent in the transmitter. Similar to the example of the data profile in the Figure 7, PW2 is shorter than PW1, so PW2 should be used for the demodulator bandwidth calculation which is found by $0.65 /$ shortest pulse width. After this value is found, the setting should be done according to Table 5. For example, if the pulse period is $100 \mu \mathrm{sec}, 50 \%$ duty cycle, the pulse width will be $50 \mu \mathrm{sec}$ ( $\mathrm{PW}=(100 \mu \mathrm{sec}$ $\times 50 \%$ ) / 100). Therefore, a bandwidth of 13 kHz would be necessary ( $0.65 / 50 \mu \mathrm{sec}$ ). However, if this data stream had a pulse period with a $20 \%$ duty cycle, then the bandwidth required would be $32.5 \mathrm{kHz}(0.65$ / $20 \mu \mathrm{sec})$. This would exceed the maximum bandwidth of the demodulator circuit. If one tries to exceed the maximum bandwidth, the pulse would appear stretched or wider.

Table 7. JP1 and JP2 Setting, 315MHz

## AGC Capacitor and Data Slicer Threshold Capacitor Selection

Capacitors C6 and C4 are $\mathrm{C}_{\mathrm{TH}}$ and $\mathrm{C}_{\mathrm{AGC}}$ capacitors respectively providing a time base reference for the data pattern received. These capacitors are selected according to data profile, pulse duty cycle, dead time between two received data packets, and if the data pattern does has or not have a preamble. See Figure 8 for example of a data profile.

PW2 = Narrowest pulse width
t1 \& t2 = data period

Figure 8. Example of a Data Profile
For best results, they should always be optimized for the data pattern used. As the baud rate increases, the capacitor values decrease. Table 8 shows suggested values for Manchester Encoded data, 50\% duty cycle.

| Open | Open | 13000 | 10 nF | $0.47 \mu \mathrm{~F}$ |

Table 8. Suggested $\mathrm{C}_{\mathrm{TH}}$ and $\mathrm{C}_{\mathrm{AGC}}$ Values
JP3 and JP4 are jumpers selectable to high or low and used to configure the digital squelch function. When it is tied to high, there is no squelch applied to the digital circuits and the DO (data out) pin has a hash signal. When the pin is low, the DO pin activity is considerably reduced. It will have more or less than shown in the figure below depending upon the outside band noise. The penalty for using squelch is a delay in getting a good signal in the DO pin. This means that it takes longer for the data to show up. The delay is dependent upon many factors such as RF signal intensity, data profile, data rate, $\mathrm{C}_{\mathrm{TH}}$ and $\mathrm{C}_{\mathrm{AGC}}$ capacitor values, and outside band noise See Figure 9 and Figure 10. Please note that Squelch action is based on the Bitcheck operation and may be optimized using the Bitcheck Window serial register setting.

Figure 9. Data Out Pin with No Squelch $(S Q=1)$

Figure 10. Data Out Pin with Squelch $(S Q=0)$
Other components used are C5, which is a decoupling capacitor for the $V_{D D}$ line; R3 for the shutdown pin (SHDN = 0, device is operation), which can be removed if that pin is connected to a microcontroller or an external switch; and R1 and R2 which form a voltage divider for the AGC pin. One can force a voltage in this AGC pin to purposely decrease the device sensitivity. Special care is needed when doing this operation, as an external control of the AGC voltage may vary from lot to lot and may not work the same in several devices.

Three other pins are worthy of comment. They are the DO, RSSI, and shutdown pins. The DO pin has a driving capability of 0.4 mA . This is good enough for most of the logic family ICs on the market today. The RSSI pin provides a transfer function of the RF signal intensity versus voltage. It is very useful to determine the signal-to-noise ratio of the RF link, crude range estimate from the transmitter source and AM demodulation, which requires a low $\mathrm{C}_{\mathrm{AGC}}$ capacitor value.
The shutdown pin (SHDN) is useful to save energy. Making its level close to $V_{D D}(S H D N=1)$, the device is not in operation. Its DC current consumption is less than $1 \mu \mathrm{~A}$ (do not forget to remove R3). When toggling from high to low, there will be a time required for the device to come to steady-state mode, and a time for data to show up in the DO pin. This time will be dependent upon many things such as temperature, the crystal used, and if there is an external oscillator with faster startup time. See Figure 11 and Figure 12 or time-to-good-data on both 433.92 MHz and 315 MHz versions.

Figure 11. Time-to-Good-Data after Shutdown Cycle, 433.92MHz, Room Temperature

Figure 12. Time-to-Good-Data after Shutdown Cycle, 315MHz at Room Temperature

## Serial Register Programming

Programming the device is accomplished by the use of pins DO and SCLK. Normally, DO (Pin 10) is outputting data and needs to switch to an input pin made by the start sequence, as shown at Figure 13. High at the SCLK pin tri-states the DO pin, enabling the external drive into the DO pin with an initial low level. The start sequence is completed by taking SCLK low, then high while DO is low, followed by taking DO high, then low while SCLK is high. The serial interface is initialized and ready to receive the programming data.

Figure 13. Serial Interface Start Sequence

Bits are serially programmed starting with the most significant bit (MSB = D19) if all bits are being programmed until the least significant bit (LSB =DO) For instance, if only the desense bits D0, D1, and D2 are being programmed, then these are the only bits that need to be programmed with the start sequence D2, D1, D0, plus the stop sequence. Or, if only the squelch bit D17 is needed, then the sequence must be from start sequence, D17 through D0 plus the stop sequence, making sure the other bits (besides D17) are programmed as needed. It is recommended that all parallel input pins (SELO, SEL1, and SQ) be kept high when using the serial interface. After the programming bits are finished, a stop sequence (as shown in Figure 14) is required to end the mode and reestablish the DO pin as an output again. To do so, the SCLK pin is kept high while the DO pin changes from low to high, then low again, followed by the SCLK pin made low. Timing of the programming bits are not critical, but should be kept as shown below:

T1 < $0.1 \mu \mathrm{~s}$, Time from SCLK to convert DO to input pin
T6 $>0.1 \mu \mathrm{~s}$, SCLK high time
T7 > $0.1 \mu \mathrm{~s}$, SCLK low time
T2, T3, T4, T5, T8, T9, T10 > $0.1 \mu \mathrm{~s}$

Figure 14. Serial Interface Stop Sequence
SCLK frequency should be greater than 5 kHz to avoid automatic reset from internal circuitry.

## Serial Interface Register Loading Examples

See Figures $15-17$. (Channel 1 is the DO pin, and channel 2 is the SCLK pin).

Figure 15. All Bits D19 through D0 $=0$

Figure 16. All Bits D19 through D0 $=1$

Figure 17. $\mathrm{D} 19=\mathrm{D} 18=1, \mathrm{D} 17=\mathrm{D} 0=0$

## Auto-Poll Programming Example

Auto-Poll example (see Figure 18):
D0 = D1 = D2 = 0, no desense
D3 = D4 = 0, demodulator bandwidth = 1712 hertz, 1 kHz baud rate, pulse $=500 \mu \mathrm{sec}$.
Required demodulator bandwidth is $0.65 / 500$ usec $=$ 1300 hertz
D5 = D6 = 1, Slice level $=50 \%$
D7 = 0, D8 = 1, bit check = 4 bits.
This is the time the device is ON checking for four consecutive valid windows.
$D 9=D 10=1, D 11=0$, data rate is $1 \mathrm{kHz},(500 \mu \mathrm{sec}$ pulses), window set to $433 \mu \mathrm{sec}$ ( $<500 \mathrm{usec}$ )
$D 12=\mathrm{D} 13=0, \mathrm{D} 14=1$, sleep timer set to 160 msec , that is, 4 bit is ON and 160 msec is OFF.
D15 = 1, device is placed in autopoll
D16 $=0$, not used. Always set to 0 .
$\mathrm{D} 17=0$, squelch is OFF
D18 = 1, watchdog timer is OFF
D19 = 0, no RSSI offset

From MSB to LSB (see Table 9):

| D19 | D18 | D17 | D16 | D15 | D14 | D13 | D12 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |
| D11 | D10 | D9 | D8 | D7 | D6 | D5 |  |
| 0 | 1 | 1 | 1 | 0 | 1 | 1 |  |
| D4 | D3 | D2 | D1 | D0 |  |  |  |
| 0 | 0 | 0 | 0 | 0 |  |  |  |

## PCB Considerations and Layout

Figure 19 to Figure 23 show the QR219BPF PCB layout. The Gerber files provided are downloadable from Micrel Website and contain the remaining layers needed to fabricate this board. When copying or making one's own boards, make the traces as short as possible. Long traces alter the matching network and the values suggested are no longer valid. Suggested matching values may vary due to PCB variations. A PCB trace 100 mills ( 2.5 mm ) long has about 1.1 nH inductance. Optimization should always be done with exhaustive range tests. Make sure the individual ground connection has a dedicated via rather then sharing a few of ground points by a single via. Sharing ground via will increase the ground path
inductance. Ground plane should be solid and with no sudden interruptions. Avoid using ground plane on top layer next to the matching elements. It normally adds additional stray capacitance which changes the matching. Do not use Phenolic materials as they are conductive above 200 MHz . Typically, FR4 or better materials are recommended. The RF path should be as straight as possible to avoid loops and unnecessary turns. Separate ground and $V_{D D}$ lines from other digital or switching power circuits (such microcontroller...etc). Known sources of noise should be laid out as far as possible from the RF circuits. Avoid unnecessary wide traces which would add more distribution capacitance (between top trace to bottom GND plane) and alter the RF parameters.
