3 Functional Description

3.1 User Accessible Data Array

A user accessible data array allows for each device to be customized. The array consists of an OTP factory programmable block, an OTP user programmable block, and read only registers for device status. The OTP blocks incorporate independent error detection circuitry for fault detection (reference [Section 3.2](#)). Portions of the factory programmable array are reserved for factory-programmed trim values. The user accessible data is shown in [Table 3](#).

3.1.1 Device Serial Number Registers

A unique serial number is programmed into the serial number registers of each device during manufacturing. The serial number is composed of the following information:

Bit Range	Content
SN[12:0]	Serial Number
SN[31:13]	Lot Number

Serial numbers begin at 1 for all produced devices in each lot and are sequentially assigned. Lot numbers begin at 1 and are sequentially assigned. No lot will contain more devices than can be uniquely identified by the 13-bit serial number. Depending on lot size and quantities, all possible lot numbers and serial numbers may not be assigned.

The serial number registers are included in the factory programmed OTP CRC verification. Reference [Section 3.2.1](#) for details regarding the CRC verification. Beyond this, the contents of the serial number registers have no impact on device operation or performance, and are only used for traceability purposes.

3.1.2 Factory Configuration Register (DEVCFG1)

The factory configuration register is a factory programmed, read only register which contains user specific device configuration information. The factory configuration register is included in the factory programmed OTP CRC verification.

Location		Bit							
Address	Register	7	6	5	4	3	2	1	0
\$04	DEVCFG1	0	0	1	0	AXIS	RNG[2]	RNG[1]	RNG[0]
Factory Default		0	0	1	0	1	0	0	0

3.1.2.1 Axis Indication Bit (AXIS)

The axis indication bit indicates the axes of sensitivity as shown below. This bit is factory programmed.

AXIS	Sensitivity Axis
0	X
1	Z

3.1.2.2 Range Indication Bits (RNG[2:0])

The range indication bits are factory programmed and indicate the full-scale range of the device as shown below.

RNG[2]	RNG[1]	RNG[0]	Full-Scale Acceleration Range	g-Cell Design	PSI5 Init Data Transmission (D9) Reference Table 13
0	0	0	Reserved	N/A	0001
0	0	1	±60g	Medium-g	0111
0	1	0	Reserved	N/A	0010
0	1	1	±120g	Medium-g	1000
1	0	0	Reserved	N/A	0011
1	0	1	±240g	High-g	1001
1	1	0	Reserved	N/A	0100
1	1	1	±480g	High-g	1010

3.1.3 Device Configuration 2 Register (DEVCFG2)

Device configuration register 2 is a user programmable OTP register that contains device configuration information.

Location		Bit							
Address	Register	7	6	5	4	3	2	1	0
\$05	DEVCFG2	LOCK_U	PCM	SYNC_PD	LATENCY	DATASIZE	BLANKTIME	P_CRC	BAUD
Factory Default		0	0	0	0	0	0	0	0

3.1.3.1 User Configuration Lock Bit (LOCK_U)

The LOCK_U bit allows the user to prevent writes to the user configuration array once programming is completed.

If the LOCK_U bit is written to '1' when a PSI5 "Execute Programming of NVM" command is executed, the LOCK_U OTP bit will be programmed. Upon completion of the OTP programming, an OTP readout will be executed, locking the array from future OTP writes. The User Programmable OTP Array Error Detection is also activated (Reference [Section 3.2.2](#)).

3.1.3.2 PCM Enable Bit (PCM)

The PCM bit enables the PCM output pin. When the PCM bit is set, the PCM output pin is active and outputs a Pulse Code Modulated signal proportional to the acceleration response. Reference [Section 3.5.3.7](#) for more information regarding the PCM output. When the PCM bit is cleared, the PCM output pin is actively pulled low.

PCM	PCM Output
0	Actively Pulled Low
1	PCM Signal Enabled

3.1.3.3 Sync Pulse Pulldown Enable Bit (SYNC_PD)

The sync pulse pulldown enable bit selects if the sync pulse pulldown is enabled once a sync pulse is detected. Reference [Section 4.2.1.2](#) for more information regarding the sync pulse pulldown.

SYNC_PD	Sync Pulse Pulldown
0	Disabled
1	Enabled

If Daisy Chain Mode is enabled, the Sync Pulse Pulldown is enabled as listed below:

SYNC_PD	Daisy Chain Address Programmed	“Run Mode” Command Received	Daisy Chain Address = ‘001’	Sync Pulse Pulldown
0	x	x	x	Disabled
1	No	x	x	Enabled
1	Yes	No	x	Disabled
1	Yes	Yes	No	Disabled
1	Yes	Yes	Yes	Enabled

3.1.3.4 Latency Selection Bit (LATENCY)

The latency selection bit selects between one of two data latency methods to accommodate synchronized sampling or simultaneous sampling. Reference [Section 4.5](#) for more information regarding latency and data synchronization.

Latency	Data Latency
0	Simultaneous Sampling Mode (Latency relative to Sync Pulse)
1	Synchronous Sampling Mode (Latency relative to Time Slot)

3.1.3.5 Data Size Selection Bit (DATASIZE)

DATASIZE	Data Length
0	10 Bits
1	8 Bits

3.1.3.6 PSI5 Sync Pulse Blanking Time Selection Bit (BLANKTIME)

The PSI5 sync pulse blanking time selection bit selects the timing for ignoring sync pulses after successful reception of a sync pulse. Reference [Section 4.2.1.1](#) for details regarding sync pulse detection and blanking.

BLANKTIME	Blanking Time Method
0	Maximum of $t_{\text{SYNC_OFF_500}}$ Or Response Transmission Complete

3.2 OTP Array CRC Verification

3.2.1 Factory Programmed OTP Array CRC Verification

The Factory programmed OTP array is verified for errors with a 3-bit CRC. The CRC verification is enabled only when the factory programmed array is locked. The CRC verification uses a generator polynomial of $g(x) = X^3 + X + 1$, with a seed value = '111'.

Once the CRC verification is enabled, the CRC is continuously calculated on all bits in registers \$00, \$01, \$02, \$03, and \$04 and on the factory programmable device configuration bits with the exception of the factory lock bit. Bits are fed in from right to left (LSB first), and top to bottom (lower addresses first) in the register map. The calculated CRC is then compared against the stored 3 bit CRC. If a CRC error is detected in the OTP array, the IDEF_B bit is cleared in the SC register.

The CRC verification is completed on the memory registers which hold a copy of the fuse array values, not the fuse array values.

3.2.2 User Programmable OTP Array Error Detection

The user programmable OTP array is independently verified for errors. The Error Detection is enabled only when the LOCK_U bit in the user data register array is set.

When a PSI5 Programming Mode "Execute Programming of NVM" command is received and the LOCK_U bit is set, the device calculates the error detection code and writes the code to NVM, enabling the Error Detection.

Once the error detection is enabled, the error detection code is continuously calculated on all bits in registers \$05, \$06, \$07, \$08, \$09, \$0A, \$0B and \$0D with the exception of the LOCK_U bit. The calculated code is then compared against the stored error code. If a mismatch is detected, the IDEN_B bit is cleared in the SC register.

The error detection is completed on the memory registers which hold a copy of the fuse array values, not the fuse array values.

3.3 Voltage Regulators

The device derives its internal supply voltage from the V_{CC} and V_{SS} pins. Separate internal voltage regulators are used for the analog (V_{REGA}) and digital circuitry (V_{REG}). The analog and digital regulators are supplied by a buffer regulator (V_{BUF}) to provide immunity from EMC and supply dropouts on V_{CC} . External filter capacitors are required, as shown in [Figure 1](#).

The voltage regulator module includes voltage monitoring circuitry which holds the device in reset following power-on until the internal voltages have increased above the under-voltage detection thresholds. The voltage monitor asserts internal reset when the external supply or internally regulated voltages fall below the under-voltage detection thresholds. A reference generator provides a reference voltage for the $\Sigma\Delta$ converter.

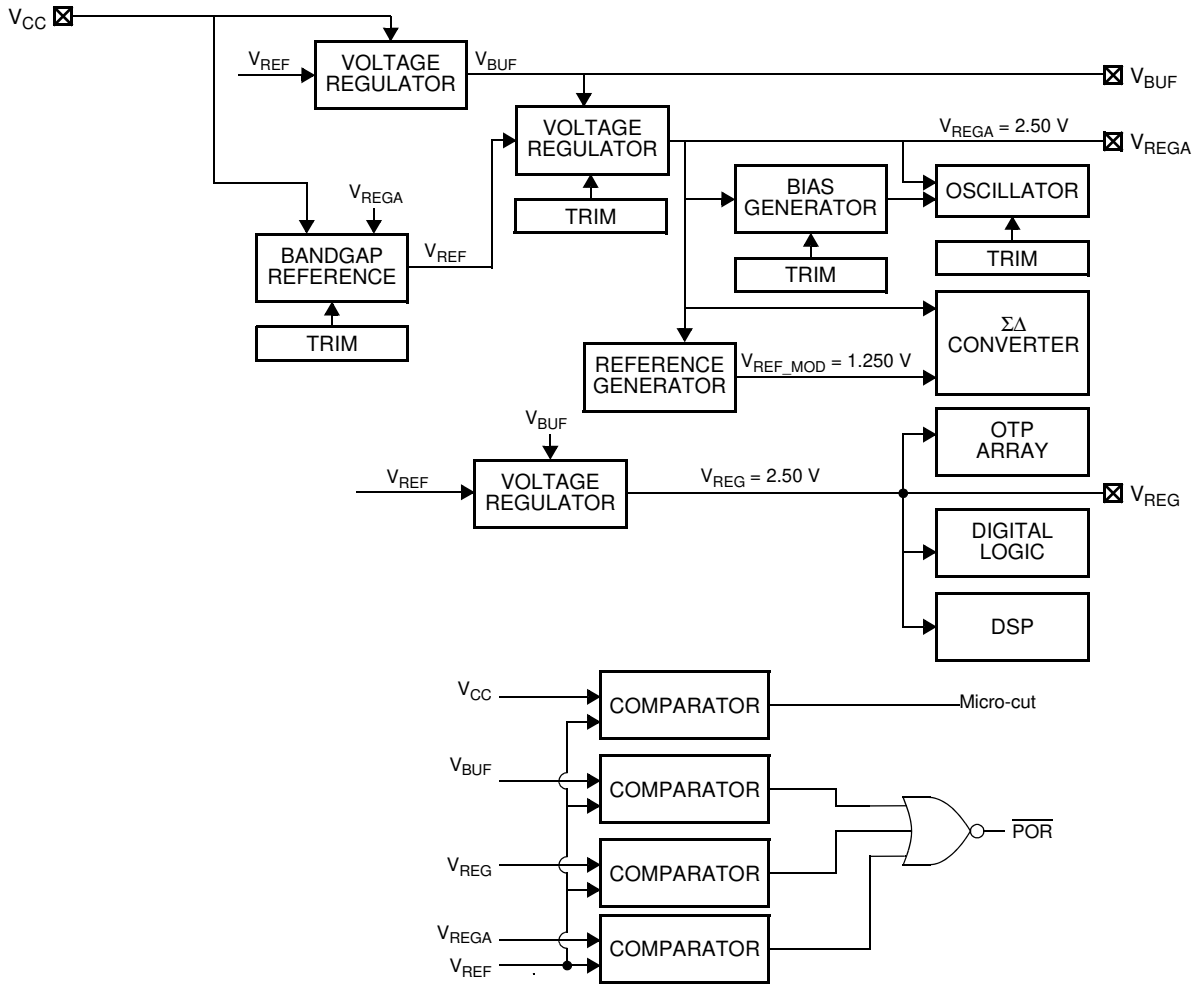

Figure 8. Voltage Regulation and Monitoring

3.3.1 V_{BUF} , V_{REG} and V_{REGA} Regulator Capacitor

The internal regulators require an external capacitor between each of the regulator pins (V_{BUF} , V_{REG} or V_{REGA}) and the associated the V_{SS} / V_{SSA} pin for stability. [Figure 1](#) shows the recommended types and values for each of these capacitors.

3.3.2 V_{CC} , V_{BUF} , V_{REG} and V_{REGA} Under-Voltage Monitor

A circuit is incorporated to monitor the supply voltage (V_{CC}) and all internally regulated voltages (V_{BUF} , V_{REG} and V_{REGA}). If any of internal regulator voltages fall below the specified under-voltage thresholds in [Section 2](#), the device will be reset. If V_{CC} falls below the specified threshold, PSI5 transmissions are terminated for the present response. Once the supply returns above the threshold, the device will respond to the next detected sync pulse. Reference [Figure 9](#).

Figure 9. V_{CC} Micro-Cut Response

3.3.3 V_{BUF} , V_{REG} , and V_{REGA} Capacitance Monitor

A monitor circuit is incorporated to ensure predictable operation if the connection to the external V_{BUF} , V_{REG} , or V_{REGA} capacitor becomes open.

In asynchronous mode, the V_{BUF} regulator is disabled $t_{CAPTEST_ADLY}$ seconds after each data transmission for a duration of $t_{CAPTEST_TIME}$ seconds. If the external capacitor is not present, the regulator voltage will fall below the internal reset threshold, forcing a device reset.

In synchronous mode, the V_{BUF} regulator is disabled $t_{CAPTEST_SDLY}$ seconds after each sync pulse for a duration of $t_{CAPTEST_TIME}$ seconds. If the external capacitor is not present, the regulator voltage will fall below the internal reset threshold, forcing a device reset.

The V_{REG} and V_{REGA} regulators are disabled at a continuous rate ($t_{CAPTEST_RATE}$), for a duration of $t_{CAPTEST_TIME}$ seconds. If either external capacitor is not present, the associated regulator voltage will fall below the internal reset threshold, forcing a device reset.
