# imall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from, Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# MTCH650/2

## Programmable Voltage Boost with Built-in Level Shifters and Serial Interface with Output Enable

#### **MTCH652 Features:**

- 19 High Voltage I/O Lines
- Built-in Boost
- Internal Switch
- 1.8V to 5.5V Input Operating Range
- Low Quiescent Current: <200 µA</li>
- Low Shutdown Current: 1.5 µA, typical
- Up to 50 mA Output Current, at VIN = 3.6V and VOUT = 12V
- The Boost is Driven by an External PWM Allowing for Greater Boost Flexibility
- Selectable Output Voltage Range: 6V, 8V, 10V, 12V, 14V, 16V and 18V
- Selectable Current Limiting
- · Selectable Soft Start
- High-Speed SPI Interface:
- 1 MHz max.
- Output Enable (OE) Independent of SPI Interface
- Built-in Discharge Circuit

#### FIGURE 1: 28-PIN SOIC, SSOP DIAGRAM

#### MTCH650 Features:

- 21 High Voltage I/O lines
- 1.8V to 5.5V Input Operating Range
- Low Quiescent Current: <200 μA</li>
- Low Shutdown Current: 1.5 µA typical
- Up to 100 mA Output Current with 5 mA per OUTxx Channel
- Output Enable (OE) Independent of SPI Interface
- 3.6 to 18V External VPPIN Range

#### Package Type:

- 28-pin SOIC, SSOP
- 28-pin UQFN (4x4)

# MTCH650/2

#### TABLE 1:PIN FUNCTION TABLE FOR MTCH650

#### INPUT VOLTAGE (VDD)

Connect the input voltage to VDD. This pin must be decoupled to GND with a recommended 1  $\mu f$  minimum capacitor.

#### BOOST VOLTAGE INPUT (VPPIN)

Boost input voltage must be decoupled to GND with recommended 1  $\mu f$  minimum capacitor.

#### OUTPUT ENABLE INPUT (OE)

When OE is set to logic '0', all output latches (OUTxx) are GND. When OE is set to logic '1', all output latches that are set to drive '1' will output the boost voltage level. The OE state is ignored and all OUTxx are high-impedance (High Z) during shutdown or soft-start transient.

#### LATCH ENABLE INPUT (LE)

Latch Enable Input (LE) is the active-low latch input used for latching-in serial data. Serial data is ignored unless LE is logic '0'. After clocking serial data, the data is internally latched when LE changes from logic '0' to logic '1'.

SERIAL DATA INPUT (DIN)

Serial data input.

SERIAL DATA CLOCK INPUT (CLK)

Serial data clock input.

HV OUTPUT (OUTXX)

High-voltage output pins.

#### INPUT VOLTAGE (VDD)

Connect the input voltage to VDD. This pin must be decoupled to GND with a recommended 1  $\mu f$  minimum capacitor.

#### BOOST VOLTAGE OUTPUT (VPP)

Boost output voltage must be decoupled to GND with a recommended 1 µf minimum capacitor.

#### BOOST INDUCTOR INPUT (LC)

The Boost Inductor Input must be decoupled to GND on the VDD side with a recommended 1  $\mu f$  minimum capacitor.

#### OUTPUT ENABLE INPUT (OE)

When OE is set to logic '0', all output latches (OUTxx) are GND. When OE is set to logic '1', all output latches that are set to drive '1' will output the boost voltage level. The OE state is ignored and all OUTxx are high-impedance (High Z) during shutdown or soft-start transient.

#### LATCH ENABLE INPUT (LE)

Latch Enable Input (LE) is the active-low latch input used for latching-in serial data. Serial data is ignored unless LE is logic '0'. After clocking serial data, the data is internally latched when LE changes from logic '0' to logic '1'.

#### SERIAL DATA INPUT (DIN)

Serial data input.

SERIAL DATA CLOCK INPUT (CLK)

Serial data clock input.

PWM INPUT (OSCIN)

PWM input signal for boost.

HV OUTPUT (OUTXX)

High-voltage output pins.

### TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

#### Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

#### http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS3000000A is version A of document DS30000000).

#### Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

Microchip's Worldwide Web site; http://www.microchip.com

Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

#### **Customer Notification System**

Register on our web site at www.microchip.com to receive the most current information on all of our products.

### 1.0 DEVICE OVERVIEW

MTCH652 is a compact boost converter, with up to 19 level shifters, which provides an easy-to-use solution for driving High Voltage (HV) outputs. MTCH650 is a line driver device, with 21 level shifters available.

The devices contain a Configuration register (CONFIG) and a data (DATA) register. The CONFIG register can be adjusted using the SPI interface, allowing for voltage changes during application time. The CONFIG register sets the output voltage, the current limit and the Soft Start settings. The DATA register configures the 19/21 bit output mask for the HV output latches. The Output Enable (OE) allows for efficient cycling of the boost voltage on the HV output latches without the delay of setting HV output latches via the serial interface. The HV output latches are set to '0' when Output Enable (OE) is '0'. The HV output latches are set to the output mask when OE is '1'.

MTCH650/2 require only a 3-wire serial interface, latch enable (LE) and two capacitors. MTCH652 requires an additional PWM and a small inductor. The PWM is used to drive the boost and allows flexibility in duty cycle and frequency. The selectable internal Soft Start limits initial in-rush currents, preventing system brownouts.

Note: While MTCH650 and MTCH652 are very similar, MTCH650 does not include a built-in boost circuit. MTCH650 will require an external boost voltage device, such as MCP16301 or the output of the MTCH652.

#### FIGURE 1-1: FUNCTIONAL BLOCK DIAGRAM FOR MTCH650

#### FIGURE 1-2: FUNCTIONAL BLOCK DIAGRAM FOR MTCH652

### 2.0 POWER-ON RESET (POR)

The on-chip POR circuit holds the device in a Reset state until VDD has reached VPOR. The POR is not configurable.

All latches are cleared when POR is active. When VDD is below VPOR, the internal shift register will reset to all '0's.

#### 3.0 SERIAL INTERFACE

The serial interface allows configuration of MTCH650/ 2 during operation. The clock and serial data stream are used to configure a 3-byte wide shift register prior to latching the desired data using Latch Enable (LE) input.

#### 3.1 Loading Data

The shift register is three bytes wide and shifts data from right to left. Therefore, data must be entered in MSB first to LSB last sequence, starting with the leading dummy bits set to zero if necessary.

The Data Word selects which HV outputs (OUTxx) are to be cycled with Output Enable (OE).

The Configuration Word sets the shutdown state, boost voltage, current limit and other miscellaneous options.

In addition, Latch Enable (LE) can serve as a chipselect. A high state on LE disables the input shift registers, allowing for sharing of the SPI bus.

The shift register is written using a clock input, CLK, and a data input, DIN. Data is read on the falling CLK edge. The master loads DIN when CLK is high. The MTCH650 will latch DIN data value on the CLK falling edae.

The contents of the shift register are then loaded into the latches using the latch enable input, LE. The LE signal is asynchronous to the clock. Data is latched on the rising edge of LE. The LE is also a chip-select. If LE is held high, then the device will not accept new serial data. The falling edge of LE re-enables data input and resets the shift register, allowing new data to be clocked-in.

In User mode, latched values are held until overwritten by new data or a POR event occurs.

See Figure 3-1 for details.

#### FIGURE 3-1: SERIAL TIMING INTERFACE

#### **Configuration Word** 3.2

The Configuration Word is selected by setting the LSB of the data stream to '0'. In User mode, using the MTCH652, the output voltage and current limit of the boost circuit can be selected.

Complete Configuration Word documentation can be found in Register 3-1.

#### 3.3 Data Word

The Data Word consists of three bytes of data which set the 21 output pins of the MTCH650, or 19 output pins of the MTCH652, low or high. The Data Word is selected by setting the LSB of the data stream to '1'.

Complete Data Word documentation can be found in Register 3-2.

#### 4.0 VOLTAGE BOOST INTERFACE

MTCH652 includes a voltage boost circuit which generates selectable High Voltage (HV) from VDD using modulated input signal in combination with external inductance and capacitance. The switch and diode are built into the device.

#### 4.1 Boost Connections

4.1.1 INPUTS

OSCIN – a modulated input signal typically derived from a PWM. The duty cycle range is typically from 60 to 90%.

VOUT<2:0> – 3-bit output voltage-select settings. Refer to Register 3-1 for configuration details.

ILIM<1:0> – 2-bit current-limit setting used to limit the maximum current the boost can draw to prevent brown-out of current-limited power supplies. Refer to Register 3-1 for configuration details.

VPPIN – HV input on MTCH650.

#### 4.1.2 OUTPUTS

VPP – HV output of the boost circuit on MTCH652.

LC – Connection for both external inductor and external capacitor for the boost circuit on MTCH652.

#### 4.2 Boost Operation

Under normal operation, OSCIN modulates the gate of the internal switching transistor to build up energy in the LC and raise VPP. The internal circuitry regulates the boost voltage based on the configuration for VOUT<2:0> and ILIM<1:0>. VOUT and ILIM can be changed by the user via the serial interface.

#### 4.3 Soft Start

The boost circuit is equipped with an automatic soft-start feature. This soft-start feature prevents a high initial in-rush current from pulling down the power supply, which will result in a brown-out condition. The current is limited to approximately 200 mA during the initial 16384 OSCIN cycles or about 16 ms with 1 MHz OSCIN frequency after enabling the boost circuit.

After the soft start has timed-out, the current limit reverts to the value selected by the ILIM<1:0> setting.

Disable soft start by setting SSDIS = 1.

#### 4.4 VPP Discharge

When the value of VOUT<2:0> is changed to a lower voltage and the circuit is active, the VPP discharge transistor is enabled until the lower new VOUT is reached. This quickly reduces VPP to the new value. If VOUT<2:0> is changed from a lower to higher voltage, VPP discharge has no effect.

### 5.0 APPLICATION INFORMATION

#### 5.1 Input Capacitor Selection

Using an input bypass capacitor reduces peak current transients drawn from the input supply and also reduces switching noise generated by the boost. Typically, a ceramic low ESR X5R or X7R capacitor between 1  $\mu$ F to 10  $\mu$ F is acceptable.

In applications that are extremely sensitive to high frequency noise, smaller caps with higher operational bandwidth may be placed in parallel with standard recommended values. In applications using much lower than an 1 MHz switching frequency, or in cases with >1A peak inductor currents, larger cap sizes may also be placed in parallel with the standard values.

#### 5.2 Output Capacitor Selection

The output capacitor helps to provide a stable output voltage during sudden load transients and reduces output voltage ripple. As with the input capacitor, X5R and X7R ceramic capacitors are well suited for this application. Typical values are 1  $\mu F$  to 10  $\mu F.$ 

Note:	Increasing the capacitance value will						
	increase the rise and fall times when						
	switching between boost voltages.						

#### 5.3 Inductor Selection

MTCH652 can be used with small surface mount inductors. Typical inductance values are  $1 \,\mu$ H to  $10 \,\mu$ H.

Note:	An	inductance	value	of	2.2	μH	is	
	recommended for initial evaluation.							

Several parameters are used to select the correct inductor, maximum rated current, saturation current and copper resistance (ESR). The input current can be much higher than the output current using a boost converter device. A lower ESR value will yield a higher efficiency rate for the converter, which is a common trade-off in component size versus efficiency.

The saturation current specifies a point at which the inductance has rolled off a percentage of the rated value. This can range from 20% to 40% reduction in inductance. As the inductance rolls off, the inductor current increases, as does the peak switch current. It is important to keep the inductance from rolling off too much, causing the switch current to reach the peak limit.

Basic inductor selection is based on a DCR < 0.25  $\Omega$  and I<sub>SAT</sub> > 1.5 x ILIM or 1.5 x IPK (L) (whichever is greater), where ILIM = selected current limit value and IPK (L) = Peak inductor current. Examples of recommended inductors are shown in Table 5-1.

#### TABLE 5-1: EXAMPLES OF RECOMMENDED INDUCTORS

Part Number	Value (µH)	DCR Ω (typ.)	ISAT (A)	Size WxLxH (mm)

#### 5.4 PCB Layout Information

Mindful layout techniques are important to any switching circuitry. When wiring high-current paths, short and wide traces should be used. It is important that the input and output capacitors be placed as close as possible to MTCH652 to minimize loop area.

The HV outputs should be routed away from the switching node and switching current loop. When possible, ground planes and traces should be used to help shield the feedback signal and also minimize noise and magnetic interference. In many cases, MTCH650/2 are used in conjunction with sensitive sensing lines. The HV outputs from the MTCH650/2 should be shielded or routed away from these sense lines to reduce noise (see Figure 5-1 and Figure 5-2).

FIGURE 5-1: MTCH652 SOIC AND SSOP RECOMMENDED LAYOUT

FIGURE 5-2: MTCH652 UQFN RECOMMENDED LAYOUT

#### 6.0 APPLICATION EXAMPLE

MTCH650/2 are very simple to set up and use, only requiring configuration of a Configuration Word and a Data Word. The difference between MTCH650 and MTCH652 is the addition of the PWM input and the selectable options for VOUT and ILIM. Figure 6-1 shows a typical application using a  $PIC^{\textcircled{R}}$  microcontroller and MTCH652.

#### 6.1 MTCH650/2 Connections

The following pins are required to drive MTCH650/2 from the host side:

- PWM Output (MTCH652 only)
- OE Output
- LE Output
- SDO<sup>(1)</sup> serial data output
- SCLK<sup>(1)</sup> serial data clock output

Note 1: These pins can be from a standard MSSP module or bit-banged.

#### 6.2 MTCH650/2 Initialization

The following shows the basic operations for initialization addressed in additional individual notes within this section:

- On the host, I/O ports to be used for OE and LE functionality should be configured as outputs. Set OE low and set LE high.
- 2. Configure the host SPI port for 1 MHz or equivalent bit-bang function. It is recommended that a function that takes the bit mask and sends it to MTCH650/2 be created. Example 6-1 shows such an example.
- 3. Host sends command to configure the MTCH650/2 CONFIG Word to default settings:
  - ILIMDIS = 0 ILO Enabled
  - VCMPSEN = 0 Synchronization Disabled
  - SSDID = 0 Soft Start Enabled
  - ILIM = 00 ILIM = 200 mA
  - VOUT = 000 Boost Disabled

4. (MTCH652 only) Configure the host PWM to output on the correct I/O pin. It is recommended that PWM starts at a frequency of 500 kHz with a 70% duty cycle. It may be necessary to later adjust the parameters to optimize the efficiency and ripple.

#### EXAMPLE 6-1: BIT-BANG CODE

{							
unsigned int x;							
MTCH65x_LE_LAT_CLR;							
// clear LE to start							
for (x=0; x<24; x++)							
{							
if (data&0x800000)							
{							
MTCH65x_DIN_LAT_SET;							
// bit is a 1							
}

uala <<- 1;							
// fotate in next bit							
ן MTCH65v IE ואד פריי							
//set IF latch in the data							
) // Set he fatti fil the data							
ſ							

#### 6.3 SPI Specifics

MTCH650/2 serial interface uses the PIC MCU MSSP SPI defaults. The specifics are:

- · De-assert LE
- The host changes the state of DIN when CLK is low, data is latched on a low-to-high transition of CLK on the MTCH650/2
- After clocking-in all serial data assert LE, this will latch the new data into the MTCH650/2 internal registers.

#### 6.4 Setting the Boost Voltage

The boost voltage is set with VOUT<2:0> in the Configuration Word. The rise and fall times for boost voltage changes are dependent on ILIM, the capacitor and on VPP. The user must ensure that, when changing boost voltages, the new VPP voltage has settled to the correct value.

#### 6.5 Low Power

For Low-Power or Shutdown modes, set VOUT<2:0> = 000. Turn off the PWM for the absolute minimum operating power mode.

# 6.6 HV Level Shifters, DATA Latches and OE

Control of the HV level shifters is accessed through the bits OUTSEL<20:0> in the Data Word. Only bits that are set in OUTSEL will have the boost voltage set on the HV level shifters when OE is asserted. All others will remain in a de-asserted state at Vss. When OE is de-asserted, all HV level shifters will be held at Vss.

The user must be aware that MTCH652 has limited current drive. Driving all HV level shifters at the same time may cause an unintended drop in boost. Alternatives for higher drive are to lower the boost voltage or use MTCH650 with an external high-voltage supply.

### 7.0 ELECTRICAL SPECIFICATIONS

#### 7.1 Absolute Maximum Ratings<sup>(†)</sup>

Ambient temperature under bias40°C to +85°C	
Storage temperature	
/oltage on pins with respect to Vss	
on LC, VPP, OUTxx0.3V to 24V	
on VDD pin0.3V to +6.0V	
on all other pins0.3V to (VDD + 0.3V)	
Total power dissipation <sup>(1)</sup>	
UQFN 2W at ambient TA = 25°C (-20 mW/C for TA > 25°C)	
SOIC 1.4W at TA = 25°C (-14 mW/C for TA > 25°C)	
Vaximum current out of Vss pin 1.5A	
Vaximum current into LC pin 1.5A	
Maximum current in/out of VPP/VPPIN pin 1.5A	
Vaximum current into VDD pin	
Clamp current, Iк (VPIN < 0 or VPIN > VDD) ±20 mA	
Vaximum output current sunk by any I/O pin 25 mA	
Vaximum output current sourced by any I/O pin	
Maximum current sourced by analog outputs, -40°C < TA < +85°C for industrial	
<b>Note 1:</b> Power dissipation is calculated as follows: PDIS = VDD x {IDD – $\sum$ IOH} + $\sum$ {(VDD – VOH) x IOH} + $\sum$ (VOL x IOL	)

<sup>†</sup> NOTICE: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure above maximum rating conditions for extended periods may affect device reliability.

#### 7.2 Standard Operating Conditions

The standard operating conditions for any device are defined as:

Operating Voltage:	$V\text{DDMIN} \leq V\text{DD} \leq V\text{DDMAX}$
Operating Temperature:	TA MIN $\leq$ TA $\leq$ TA MAX

#### VDD — Operating Supply Voltage

MTCH650/2	
VDDMIN	
VDDMAX	
TA — Operating Ambient Temperature Range	
Industrial Temperature	
ТА_МІN	-40°C
Та_мах	

**Note 1:** Maximum current rating requires even load distribution across I/O pins. Maximum current rating may be limited by the device package power dissipation characterizations, see Table 7-6: "Thermal Characteristics" to calculate device specifications.

NOTES:

#### 8.0 TYPICAL PERFORMANCE CURVES

The graphs and tables provided in this section are for design guidance and are not tested.

**Note:** The graphs and tables provided following this note are a statistical summary based on a limited number of samples and are provided for informational purposes only. The performance characteristics listed herein are not tested or guaranteed. In some graphs or tables, the data presented may be outside the specified operating range (e.g., outside specified power supply range) and therefore, outside the warranted range.

"Typical" represents the mean of the distribution at 25°C. "MAXIMUM", "Max.", "MINIMUM" or "Min." represents (mean +  $3\sigma$ ) or (mean -  $3\sigma$ ) respectively, where  $\sigma$  is a standard deviation, over each temperature range.

FIGURE 8-6: RIPPLE ON VPP AND OUT00; VDD = 3.3V, VPP = 18V, CVPP (C2) = 10 μF

FIGURE 8-7: RIPPLE ON VPP AND OUT00; VDD = 3.3V, VPP = 18V, CVPP (C2) = 1 μF
