2Mb Ultra-Low Power Asynchronous CMOS SRAM

128Kx16 bit

Overview

The N02L6181A is an integrated memory device containing a 2 Mbit Static Random Access Memory organized as 131,072 words by 16 bits. The device is designed and fabricated using ON Semiconductor's advanced CMOS technology to provide both high-speed performance and ultra-low power. The base design is the same as ON Semiconductor's N02L63W3A, which is processed to operate at higher voltages. The device operates with a single chip enable (\overline{CE}) control and output enable (\overline{OE}) to allow for easy memory expansion. Byte controls (\overline{UB} and \overline{LB}) allow the upper and lower bytes to be accessed independently. The N02L6181A is optimal for various applications where low-power is critical such as battery backup and hand-held devices. The device can operate over a very wide temperature range of -40°C to $+85^{\circ}\text{C}$ and is available in JEDEC standard packages compatible with other standard 128Kb x 16 SRAMs.

- When $\overline{\text{UB}}$ and $\overline{\text{LB}}$ are in select mode (low), I/O₀ - I/O₁₅ are affected as shown. When $\overline{\text{LB}}$ only is in the select mode only I/O₀ - I/O₇ are affected as shown. When $\overline{\text{UB}}$ is in the select mode only I/O₈ - I/O₁₅ are affected as shown.
- When the device is in standby mode, control inputs ($\overline{\text{WE}}$, $\overline{\text{OE}}$, $\overline{\text{UB}}$, and $\overline{\text{LB}}$), address inputs and data input/outputs are internally isolated from any external influence and disabled from exerting any influence externally.
- When $\overline{\text{WE}}$ is invoked, the $\overline{\text{OE}}$ input is internally disabled and has no effect on the circuit.

This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operating section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

1. Typical values are measured at V_{CC}=V_{CC} Typ., T_A=25°C and are not 100% tested.
2. This parameter is specified with the outputs disabled to avoid external loading effects. The user must add current required to drive output capacitance expected in the actual system.
3. This device assumes a standby mode if the chip is disabled (\overline{CE} high). In order to achieve low standby current all inputs must be within 0.2 volts of either V_{CC} or V_{SS}

Power Savings with Page Mode Operation ($\overline{WE} = V_{IH}$)

Note: Page mode operation is a method of addressing the SRAM to save operating current. The internal organization of the SRAM is optimized to allow this unique operating mode to be used as a valuable power saving feature.

The only thing that needs to be done is to address the SRAM in a manner that the internal page is left open and 16-bit words of data are read from the open page. By treating addresses A0-A3 as the least significant bits and addressing the 16 words within the open page, power is reduced to the page mode value which is considerably lower than standard operating currents for low power SRAMs.
