

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

ATAB663211A Development Board

ATAN0111

Introduction

The development board for the Atmel® ATA663211 is designed to give users a quick start using these ICs and prototyping and testing new designs. The Atmel ATA663211 is a fully integrated LIN transceiver complying with the LIN 2.0, 2.1, 2.2, 2.2A specification and SAEJ2602-2.

The IC is the interface between the LIN protocol handler and the physical layer and is designed to handle the low-speed data communication in vehicles for example in convenience electronics. Improved slope control on the LIN bus ensures secure data communication of up to 20kBaud.

This document has been created as a quick start guide for using the development board of the Atmel ATA663211. Please refer to the corresponding datasheet for more detailed information about the Atmel ATA663211 itself.

Figure 1. Atmel ATAB663211A Development Board

Development Board Features

The development board for the Atmel® ATA663211 supports the following features:

- Includes All Components Necessary for Atmel ATA663211 Operation
- All Pins Are Easily Accessible
- Can Be Used for Master or Slave Operation
- Wake-up Pulse via an On-board Switch
- Dual footprint for both available packages: DFN8 and SO8

Quick Start

The development board for the Atmel ATA663211 is shipped with all components necessary to immediately start the development of a LIN slave node.

Connecting an external 12V DC power supply between the terminals VBAT and GND puts the IC in fail-safe mode. In this mode, the INH pin is switched to the VS level which can be used to enable an external voltage regulator (not included on the board). The LIN pin is in the recessive state.

Please note that the communication is still inactive during fail-safe mode.

To communicate via the LIN bus interface, you have to switch the device into normal mode by applying a high level (for example 5V) at pin EN.

As RXD is an open-drain output, the required pull-up resistor R2 can be activated by applying +5V DC voltage, on the designated pin on the board.

1. Hardware Description

In the following sections only the normal operating conditions are described. Refer to the corresponding datasheet for detailed information about the features mentioned.

1.1 Power Supply (VBAT, +5V and GND)

The development board requires an external 5.7V to 27V DC power supply between the terminals VBAT and GND. The input circuit is protected against inverse polarity with the protection diode D1, resulting in a difference between the VBAT and VS level of approximately 0.7V.

The DC voltage at pin +5V is only required for activating the pull-up resistor for the pin RXD.

1.2 LIN Interface (LIN, TXD and RXD)

1.2.1 Bus Pin (LIN)

A low-side driver with internal current limitation, thermal shutdown, and an internal pull-up resistor in compliance with LIN spec 2.x is implemented. The internal pull-up resistor is active in normal and fail-safe mode. The LIN receiver thresholds are compatible with the LIN protocol specification. The reverse current from the LIN bus to Vs is $<2\mu\text{A}$, even when Vbat is disconnected.

At a short circuit between LIN and V_{Battery} , the output limits the output current. Due to the power dissipation, the chip temperature exceeds the overtemperature threshold and the LIN output is switched off. The chip cools down and after the temperature hysteresis the output switches on again. RXD stays high because LIN is high.

On the board the LIN pin is assembled with a 220-pF capacitor to ground. Additionally, the two extra components diode D2 (LL4148) in series with resistor R3 ($1\text{k}\Omega$) required for using the development board for a LIN master application have designated placeholders for convenient mounting.

1.2.2 Input/Output Pin (TXD)

In normal mode the TXD pin is the microcontroller interface for controlling the state of the LIN output. TXD must be pulled to ground in order to drive the LIN bus low. If TXD is high, the LIN output transistor is turned off and the bus is in the recessive state. If the TXD pin stays at GND level while switching into normal mode, it must be pulled to high level longer than $10\mu\text{s}$ before the LIN driver can be activated. This feature prevents the bus line from being accidentally driven to dominant state after normal mode has been activated (also in case of a short circuit at TXD to GND). During fail-safe mode, this pin is used as output and signals the fail-safe source.

The TXD pin provides a pull-down resistor in order to have a defined level if TXD is disconnected. An internal timer prevents the bus line from being driven permanently in the dominant state. If TXD is forced to low longer than $t_{\text{dom}} > 20\text{ms}$, the LIN bus driver is switched to the recessive state. Nevertheless, when switching to sleep mode, the actual level at the TXD pin is relevant. To reactivate the LIN bus driver, switch TXD to high ($> 10\mu\text{s}$).

1.2.3 Output Pin (RXD)

This pin reports the state of the LIN bus to the microcontroller. LIN high (recessive state) is indicated by a high level at RXD, LIN low (dominant state) is indicated by a low level at RXD. The output is an open drain, therefore it is compatible with a 3.3V or 5V power supply. The output is short circuit protected.

Please note that the ATA663211 has to be in normal mode in order to have the communication via LIN enabled.

After a wake-up the device is in fail-safe mode and the RXD pin switches to low in order to interrupt the microcontroller.

1.3.3 WAKE Input Pin (WKin)

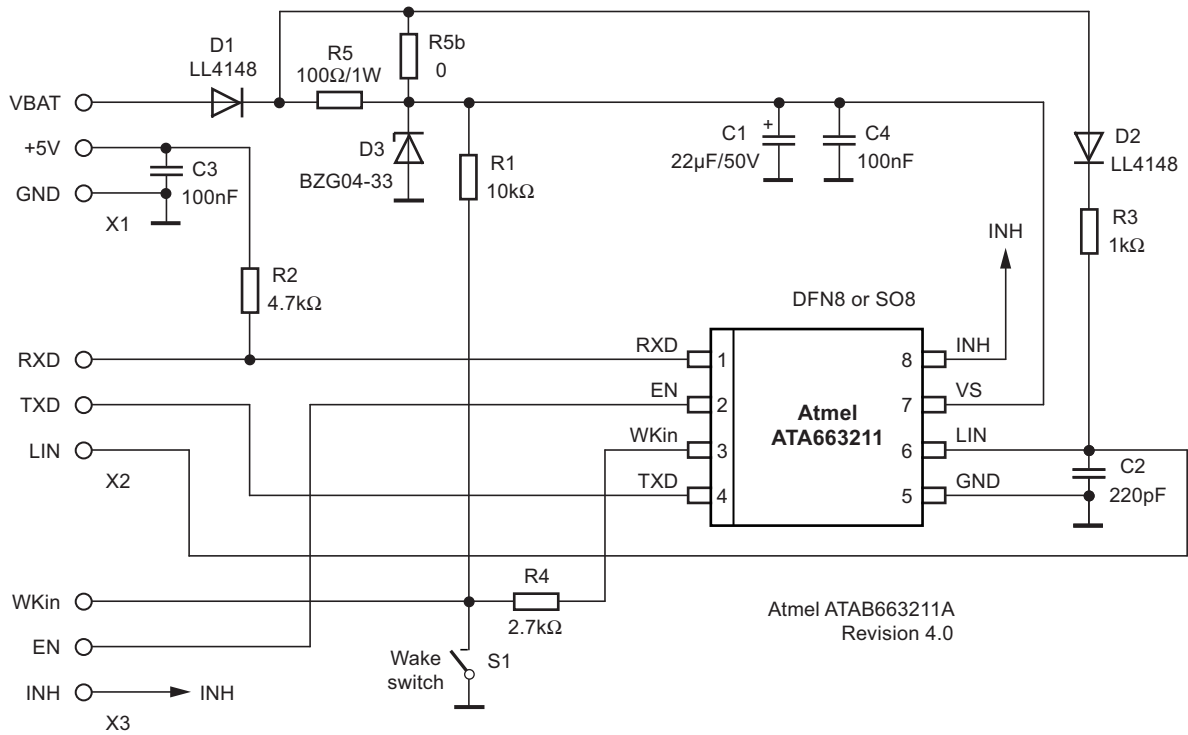

This pin is a high voltage input used to wake up the device from sleep mode. It is usually connected to an external switch in order to generate a local wake-up. A pull-up current source with typically $-10\mu\text{A}$ is implemented as well as a debounce timer. On the development board there is the push button S1 to generate a local wake-up by pulling the WKin pin to GND. The resistor $R4 = 2.7\text{k}\Omega$ is needed to limit the input current in the case of voltage transients.

Even if the WKin pin is pulled to GND, it is possible to switch the IC into sleep mode.

If no local wake-up is required for the application, the WKin pin can be connected directly to the VS pin.

2. Schematic and Layout of the Atmel ATAB663211A Development Board

Figure 2-1. Schematic of the ATAB663211A Development Board

- Notes:
1. D2 and R3 are only required for a master node.
 2. R5 and D3 are not used, R5b is 0Ω.
