

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Ultra Low Voltage Detectors

Features

- Factory-Set Reset Threshold Voltages for Nominal Supplies from 1.2V to 1.8V
- Low power consumption : Typ 7.5 μ A
- Five different timeout periods available: 70 μ s(voltage detector), 1.5ms, 30ms, 210ms and 1.68s
- Output configuration: Push-pull $\overline{\text{RESET}}$, push-pull RESET or open-drain $\overline{\text{RESET}}$
- Guaranteed reset valid to Vcc: 0.9V--active low, 0.85V--active high
- Detect voltage accuracy: $\pm 1.5\%$
- Adjustable threshold reset-in option
- Immune to short negative Vcc transients
- Small SOT23-3L, SC70-3L or SOT143-4L packages

Pad Configuration

Description

The PT7M6832–6840 are microprocessor (μ P) supervisory circuits used to monitor low-voltage power supplies in μ P and digital systems. They provide excellent circuit reliability and low cost by eliminating external components and adjustments when used with +1.2V to +1.8V powered circuits.

These devices assert a reset signal whenever the VCC supply voltage declines below a preset threshold or whenever manual reset ($\overline{\text{MR}}$) is asserted. Reset remains asserted for a fixed timeout delay after VCC has risen above the reset threshold or when manual reset is deasserted. Five different timeout periods are available: 70 μ s (voltage detector), 1.5ms, 30ms, 210ms, and 1.68s. Reset thresholds suitable for operation with a variety of supply voltages are available.

The PT7M6832/PT7M6835/PT7M6838 have a push-pull active-low reset output ($\overline{\text{RESET}}$). The PT7M6833/PT7M6836/PT7M6839 have a push-pull active-high reset output (RESET) and the PT7M 6834/ PT7M 6837/ PT7M 6840 have an open-drain active-low reset output ($\overline{\text{RESET}}$). The open-drain active-low reset output requires a pull-up resistor that can be connected to a voltage higher than VCC.

The PT7M6835/PT7M6836/PT7M6837 feature a debounced manual reset input (MR), while the PT7M6838/PT7M6839/PT7M6840 provide a RESET-IN input allowing the user to externally adjust the reset threshold. The reset comparator is designed to ignore fast transients on VCC.

Low supply current of 7.5 μ A makes the PT7M6832–PT7M6840 ideal for use in portable equipment. These devices are available in 3-pin SOT23 or 4-pin SOT143 packages.

Functional Description

Reset Output

The PT7M6832–PT7M6840 assert a reset to prevent code-execution errors during power-up, power-down, or brownout conditions. They also assert a reset signal whenever the V_{CC} supply voltage falls below a preset threshold (PT7M6832–PT7M6837) or RESET-IN falls below the adjustable threshold (PT7M6838-PT7M6840), keeping reset asserted for a fixed timeout delay (Table 2) after V_{CC} or RESET-IN has risen above the reset threshold. The PT7M6832/6835/6838 use a push-pull active-low output, the PT7M6833/6836/6839 have a push-pull active-high output, and the PT7M6834/6837/ 6840 have an open-drain active- low output stage. Connect a pull-up resistor on the PT7M6834/6837/ 6840's RESET output to any supply between 0 and 6V.

Manual Reset Input

Reset remains asserted while \overline{MR} is low, and for a fixed timeout delay after \overline{MR} returns high. This input has an

internal 20k Ω pull-up resistor, so it can be left open if it is not used. \overline{MR} can be driven with CMOS logic level, or with open-drain/collector outputs. To create a manual reset function, connect a normally open momentary switch from \overline{MR} to ground; external debounce circuitry is not required.

RESET-IN

The PT7M6838/6839/6840 features a RESET-IN input for monitoring supply voltages down to 0.44V. An external resistive-divider network can be used to set voltage monitoring thresholds as shown in Fig.3. As the monitored voltage falls, the voltage at RESET-IN decreases and asserts a reset when it falls below the RESET-IN threshold (V_{RSTIN}). The low-leakage current at RESET-IN allows for relatively large-value resistors to be used, which reduce power consumption. For example, for a 0.6V monitored trip level, if $R_2 = 200k\Omega$, then $R_1 = 70.3k\Omega$.

Note: The minimum V_{CC} of 1.3V is required to guarantee the RESET-IN threshold accuracy.

Application Information

Negative-Going VCC Transients

In addition to issuing a reset to the μP during power-up, power-down, and brownout conditions, the PT7M6832–PT7M6840 are relatively immune to short-duration negative-going Vcc transients. A 0.1 μF bypass capacitor mounted as close as possible to the Vcc pin provides additional transient immunity.

Valid Reset Output Down to Vcc = 0

When $\overline{\text{RESET}}$ falls below 0.9V, the PT7M6832/6835/6838 push-pull $\overline{\text{RESET}}$ output no longer sinks current for it becomes an open circuit. Therefore, high-impedance CMOS logic inputs connected to $\overline{\text{RESET}}$ can drift to undetermined voltages. This presents no problem in most applications since most μP and other circuitry are inoperative with Vcc lower than 0.9V. However, in applications where $\overline{\text{RESET}}$ must be valid down to 0, adding a pull-down resistor to $\overline{\text{RESET}}$ causes any stray leakage currents to flow to ground, holding $\overline{\text{RESET}}$ low (Fig.4). R3's value is not critical; 100k Ω is large enough not to load $\overline{\text{RESET}}$ and small enough to pull $\overline{\text{RESET}}$ to ground.

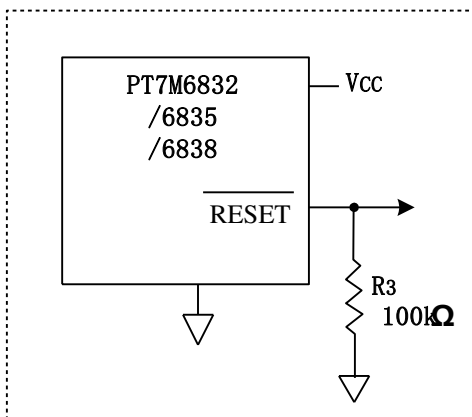

Fig.4 $\overline{\text{RESET}}$ output valid to VCC=0 circuit

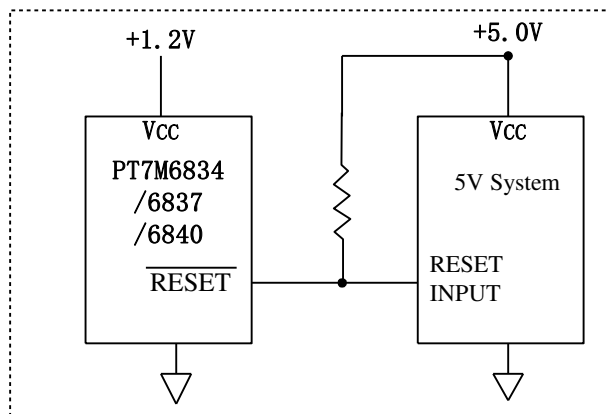

Fig.6 Open-drain $\overline{\text{RESET}}$ output with multiple supplies

A 100k Ω pull-up resistor to Vcc is also recommended for the PT7M6833/PT7M6836/PT7M6839 if $\overline{\text{RESET}}$ is required to remain valid for Vcc < 0.85V.

Interfacing to μPs with Bidirectional Reset Pins

Since the $\overline{\text{RESET}}$ output on the PT7M6834/6837/6840 is open-drain, these devices interface easily with μPs that have bidirectional reset pins. Connecting the μP supervisor's $\overline{\text{RESET}}$ output directly to the μP 's $\overline{\text{RESET}}$ pin with a single pull-up resistor allows either device to assert a reset (Fig.5).

Open-Drain $\overline{\text{RESET}}$ Output with Multiple Supplies

In some systems the open-drain output is used to level-shift from the monitored supply to reset circuitry powered by some other supply (Fig.6).

Note: As the PT7M6834/6837/6840's Vcc decreases, so does the IC's ability to sink current at $\overline{\text{RESET}}$. Also, with any pull-up, $\overline{\text{RESET}}$ will be pulled high as Vcc declines toward 0. The voltage where this occurs depends on the pull-up resistor value and the voltage to which it is connected.
