## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## Summary and Features

- Single stage power factor correction and accurate constant current (CC) output
- Low cost, low component count and small PCB footprint solution
- Superior performance and end user experience
- >100:1 dimming range even with low cost leading edge TRIAC dimmers
- Clean monotonic start-up - no output blinking
- Fast start-up ( $<300 \mathrm{~ms}$ ) - no perceptible delay
- Consistent dimming performance unit to unit
- Highly energy efficient
- $>73 \%$ at 115 VAC / 230 VAC (dimmable configuration)
- $>78 \%$ at 115 VAC / 230 VAC (non-dimmable configuration)
- Integrated protection and reliability features
- Output open-circuit protected / output short-circuit protected with auto-recovery
- Auto-recovering thermal shutdown with large hysteresis protects both components and printed circuit board
- No damage during brown out conditions
- Extended pin creepage distance between device DRAIN pin and other pins for reliable operation in high pollution and humid environments
- Meets IEC ringwave and EN55015 conducted EMI
- PF >0.9 at 115 VAC / 230 VAC
- $\%$ ATHD $<10 \%$ at 115 VAC and $<15 \%$ at 230 VAC
- Meets EN61000-3-2 harmonics contents

## PATENT INFORMATION

The products and applications illustrated herein (including transformer construction and circuits external to the products) may be covered by one or more U.S. and foreign patents, or potentially by pending U.S. and foreign patent applications assigned to Power Integrations. A complete list of Power Integrations' patents may be found at www.powerint.com. Power Integrations grants its customers a license under certain patent rights as set forth at [http://www.powerint.com/ip.htm](http://www.powerint.com/ip.htm).

## Important Note:

This board is designed for non-isolated application and the engineering prototype has not been agency approved. Therefore, all testing should be performed using an isolation transformer to provide the AC input to the prototype board.

## 1 Introduction

This document is an engineering report describing a non-isolated LED driver (power supply) utilizing a LNK457DG from the LinkSwitch-PL family of devices.

The RD-251 provides a single constant current output of 350 mA over an LED string voltage of 12 V and 18 V . The output current can be reduced using a standard $A C$ mains TRIAC dimmer down to $1 \%$ ( 3 mA ) without instability and flickering of the LED load. The board is compatible with both low cost leading edge and more sophisticated trailing edge dimmers.

The board was optimized to operate over the universal AC input voltage range (85 VAC to $265 \mathrm{VAC}, 47 \mathrm{~Hz}$ to 63 Hz ) but suffers no damage over an input range of 0 VAC to 300 VAC. This increases field reliability and lifetime during line sags and swells. LinkSwitchPL based designs provide a high power factor ( $>0.9$ ) meeting current international requirements and enabling a single design to be used worldwide.

The form factor of the board was chosen to meet the requirements for standard pear shaped (A19) LED replacement lamps. The output is non-isolated and requires the mechanical design of the enclosure to isolate the output of the supply and the LED load from the user.

The document contains the power supply specification, schematic, bill of materials, transformer documentation, printed circuit layout, and performance data.

Figure 1 - Populated Circuit Board Photograph (Top).

Figure 2 - Populated Circuit Board Photograph (Bottom).

Figure 3 - Example of RD-251 Used in an A19 LED Replacement Lamp (board removed from housing).

## 2 Power Supply Specification

The table below represents the minimum acceptable performance of the design. Actual performance is listed in the results section.

## 3 Schematic

Note:
C1, R22 and C12 are not populated.
For non-dimming application, the Active Damper and Bleeder blocks can be removed allowing the following parts can be deleted: Q3, R20, R3, R4, R10, R11 C6 and C3. Replace $0 \Omega$ for the following locations: R7, R8, and R20.

For high line only application and to match high leakage dimmer such as REV 300 W, Busch 2250 ( 600 W) or alike the following parts can be tuned. Replace F1 to $47 \Omega / 2 W$ fusible resistors, $R 7$ and $R 8$ to 20S, C6 to $220 \mathrm{nF}, R 10$ and $R 11$ to $510 \Omega / 0.5 \mathrm{~W}$ minimum, C3 to 150 nF and $R 16$ to $1 \mathrm{k} \Omega / 0.25 \mathrm{~W}$.

Figure 4 - Schematic (highlighted blocks may be removed for non-dimming applications.)

## 4 Circuit Description

This circuit is configured as non-isolated discontinuous flyback converter designed to drive LED strings at voltages of 12 V to 18 V with an output current of 350 mA . The driver is guaranteed to operate across a wide range input voltage range and provide high power factor. The circuit meets both line surge and EMI requirements and the low component count allows board dimensions required for LED bulb replacement applications.

### 4.1 Dimming Performance Circuit Design Considerations

The requirement to provide output dimming with low cost, TRIAC base, leading edge phase dimmers introduces a number of trade offs in the design.

Due to the much lower power consumed by LED based lighting the line current drawn by the overall lamp is typically below the holding current of the TRIAC within the dimmer. This causes undesirable behaviors such as limited dim range and/or flickering. The relatively large impedance the LED driver presents to the line allows significant ringing to occur when the TRIAC turns on. At the instant the TRIAC conducts, a large inrush current flows into the input capacitance of the driver, exciting the line inductance and causing current ringing. This too can cause similar undesirable behavior as the ringing may cause the TRIAC current to fall to zero and turn off, also generating flicker.

To overcome these issues the circuit includes two circuit blocks labeled active damper and bleeder. The drawback of these blocks is increased dissipation and therefore reduced efficiency of the supply.

The values used for the damper and bleeder in this design allow correct operation of a single board with the widest range of $\leq 600 \mathrm{~W}$ dimmer models including low cost leading edge TRIAC models across the full input voltage range. The trade off decision was to give flicker free operation for a single lamp connected to a dimmer operating at high line.

A single lamp operating at high line results in the lowest current drawn from the line and the highest inrush current (when the TRIAC fires) and represents the worst case. As a result the active damper and bleeder networks were designed to be aggressive; lower impedance for the bleeder and higher impedance for the damper. This increases dissipation and therefore lowers efficiency of the driver and efficacy of the overall system.

Requiring multiple lamps to be connected to a single dimmer for correct operation reduces the current required through the bleeder, allowing increasing the values of R10 and R11 and reducing the value of C6.

Limiting operation to low line only ( 85 VAC to 132 VAC) allows the values of R7 and R8 to be reduced as the peak currents that occur when a leading edge dimmer TRIAC fires are significantly lower.

Both changes reduce dissipation and improve efficiency.

For non-dimming application these components can simply be omitted and jumpers used to replace R7 and R8 giving higher efficiency with no change in other performance characteristics.

### 4.2 Input EMI Filtering and Input Rectification

The EMI filter was optimized to minimize the impact on dimming performance. Resistor R20 is a fusible resistor. Fusible types are selected to fail open-circuit should a component failure cause excessive input current. Film types (vs. wirewound) are acceptable compared to a non or passive PFC solution. This reduces the instantaneous dissipation as the input capacitance charges, however, a 2 w rating is recommended for designed that operate at high line. In addition they limit the inrush current caused when a phase leading TRIAC dimmer turns on and capacitors C4 and C5 charge. The worst case condition (maximum inrush current) occurs when the TRIAC turns on at 90 or 270 degrees, which correspond to the peaks of the AC waveform. Finally they act to damp any current ringing between the AC line impedance and the input stage of the supply again caused by the inrush current when leading edge TRIAC dimmers turn on.

Two differential pi (п) filter EMI stages are used with C1, R2, L1 and C2 forming one stage and C4, L2, R9 and C5 the second. It was found during testing that C1 was not required to meet conducted EMI limits and was therefore not populated.

The incoming AC is rectified by BR1 and filtered by C4 and C5. The total effective input capacitance, the sum of C4, C5 and C6, was selected to assure correct zero crossing detection of the AC input by the LinkSwitch-PL device, necessary correct operation and best performance during dimming.

### 4.3 Active Damper

The active damper network is used to limit the inrush current, associated voltage spikes and ringing when the TRIAC within a dimmer turns on. This connects a resistance (R7 and R8) in series with the input rectifier for a short period of each AC half-cycle, it is then bypassed for the remainder of the AC cycle by a parallel SCR (Q3). Resistor R3, R4 and C3 determines the delay before the turn-on of Q3.

### 4.4 Bleeder

Resistor R10, R11 and C6 form a bleeder network which ensures the initial input current is high enough meet the TRIAC holding current requirement, especially during small TRIAC conduction angles.

For non-dimming application, both the active damper and bleeder network may be removed. To achieve this, the following parts can be deleted: Q3, R20, R3, R4, R10, R11, C6 and C3. Replace $0 \Omega$ for the following locations: R7, R8, and R20.

### 4.5 LinkSwitch-PL Primary

The LNK457DG device (U1) incorporates the power switching device, oscillator, output constant current control, start-up, and protection functions. The integrated 725 V MOSFET provides extended voltage margin and ensures high reliability even during line surge events. The device is powered from the BYPASS pin via the decoupling capacitor C9. At start-up, C9 is charged by U1 from an internal current source via the DRAIN pin and then during normal operation it is supplied by the output via R15 and D4.

The rectified and filtered input voltage is applied to one end of the primary winding of T1. The other side of the transformer's primary winding is driven by the integrated MOSFET in U1. The leakage inductance drain voltage spike is limited by an RCD-R clamp consisting of D2, R13, R12, and C7.

Diode D6 is used to protect the IC from negative ringing (drain voltage ringing below source voltage) when the MOSFET is off due to the reflected output voltage exceeding the DC bus voltage, the result of minimal input capacitance to give high power factor.

### 4.6 Output Rectification

The secondary of the transformer is rectified by D5 and filtered by C11. A Schottky barrier type was selected for higher efficiency. As C11 provides energy storage during AC zero crossings its value determines the magnitude of the line frequency output ripple ( $2 \times f_{L}$ due to full wave rectification). The value may therefore be adjusted based on the desired output ripple. For the $680 \mu \mathrm{~F}$ value shown the output ripple is $\pm 50 \%$ of $\mathrm{l}_{\mathrm{O}}$. Resistor R17 and C10 damp high frequency ringing and improve conducted and radiated EMI.

### 4.7 Output Feedback

The CC mode set-point is determined by the voltage drop that appears across R18 which is then fed to the FB pin of U1. Output overvoltage protection is provided by VR2 and R14 (the effect of R14 on the current sense signal in negligible and can be ignored).

| ODS |  |  | 1.29 | mm | Maximum Outside Diameter for Triple Insulated Wire |

## 8 Transformer Specification

### 8.1 Electrical Diagram

Figure 7 - Transformer Electrical Diagram.

### 8.2 Electrical Specifications

| Electrical Strength | 3 second, 60 Hz, from pins 1-2 to pins 6-7 | 500 VAC |
| :--- | :--- | :---: |
| Primary Inductance | Pins 1-2, all other windings open, measured at 100 kHz, <br> 0.4 VRMS | $660 \mu \mathrm{H}, \pm 10 \%$ |
| Resonant Frequency | Pins 1-2, all other windings open | 1200 kHz (Min.) |
| Primary Leakage <br> Inductance | Pins 1-2, with pins 7-9 shorted, measured at 100 kHz, <br> 0.4 VRMS | $15 \mu \mathrm{H}$ (Max.) |

### 8.3 Materials

| Item | Description |
| :---: | :--- |
| $[1]$ | Core: EE16/PC40 |
| $[2]$ | Bobbin: EE16, Horizontal, 10 pins, (5/5), TF1613 (Taiwan Shulin) or equivalent. |
| $[3]$ | Magnet wire: \#28 AWG double coated. |
| $[4]$ | Magnet wire: \#35 AWG double coated. |
| $[5]$ | Tape: 3M 1298 Polyester Film, 8.0 mm wide, 2.0mils thick or equivalent. |
| $[6]$ | Varnish. |

### 8.4 Transformer Build Diagram

Figure 8 - Transformer Build Diagram.

Figure 9 - Transformer Assembly.

### 8.5 Transformer Construction

| Winding Preparation | Place bobbin on the mandrel such that primary on the left and secondary on the right. Winding direction is clock-wise direction. |
| :---: | :---: |
| WD1 $1^{\text {st }}$ Half of Secondary | Start at pin 7, wind 10 bifilar turns of wire item [3] from right to left, and terminate at pin 3. |
| Insulation | 1 layer of tape item [5]. |
| $\begin{gathered} \text { WD2 } \\ \text { Primary } \end{gathered}$ | Start at pin 2, wind 130 turns of wire item [4] in 3 layers: $44 \mathrm{~T}+43 \mathrm{~T}+43 \mathrm{~T}$, place 2 layers of tape item [5] between layers, see fig. 7 above, and terminate at pin 1. |
| Insulation | 1 layer of tape item [5]. |
| WD3 $2^{\text {nd }}$ Half of Secondary | Start at pin 3, wind 10 bifilar turns of wire item [3] from left to right, and terminate at pin 6. |
| Insulation | 2 layers of tape item [5]. |
| Finish | Grind core halves to get $660 \mu \mathrm{H}$ assemble with tape. Varnish. |
