## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

RT2652

## 2A, 1.2MHz Synchronous Step-Down Converter

## General Description

The RT2652 is a high efficiency synchronous, step-down DC-DC converter. The available input voltage range is from 2.7 V to 5.5 V the regulated output voltage is adjustable from 0.6 V to VIN while delivering up to 2 A of output current. The internal synchronous low on-resistance power switches increase efficiency and eliminate the need for an external Schottky diode. The switching frequency is fixed internally at 1.2 MHz . The $100 \%$ duty cycle provides low dropout operation extending battery life in portable systems. Current mode operation with internal compensation allows the transient response to be optimized. The RT2652 is available in the WDFN-10L $3 \times 3$ package.

## Ordering Information

Note :
Richtek products are :

- RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- Suitable for use in SnPb or Pb -free soldering processes.

## Features

- High Efficiency : Up to 95\%
- Fixed Frequency : 1.2MHz
- No Schottky Diode Required
- Internal Compensation
- 0.6V Reference Allows Low Output Voltage
- 100\% Duty Cycle for Low Dropout Operation
- OCP, UVP, OTP
- RoHS Compliant and Halogen Free

## Applications

- Enterprise Servers
- Ethernet Switches \& Routers
- Global Storage
- Telecom \& Industrial
- Cell Phones \& DSC's

## Pin Configuration

WDFN-10L $3 \times 3$

## Marking Information

## Simplified Application Circuit

Functional Pin Description

| Pin No. | Pin Name | Pin Function |
| :---: | :--- | :--- |
| 1 | EN | Enable Control Input. Pull high to turn on. Do not float. |
| 2,3 | VIN | Power Input. Decouple this pin to GND with a $22 \mu$ F ceramic capacitor at least. |
| 4,6 | AGND | Analog Ground. |
| 5 | FB | Feedback Voltage Input. This pin receives the feedback voltage from an external <br> resistive divider connected across the output. |
| 7,8 | LX | Power MOSFET Switch Node. Connect this pin to the inductor. |
| 9,10, <br> 11 (Exposed Pad) | PGND | Power Ground. The exposed pad must be soldered to a large PCB and <br> connected to GND for maximum power dissipation. |

## Functional Block Diagram

## Operation

The RT2652 is a monolithic, constant-frequency, current mode step-down DC-DC converter. During normal operation, the internal high side MOSFET is turned on at the beginning of each cycle. Current in the inductor increases until the peak inductor current reaches the value defined by the internal error amplifier. The error amplifier adjusts the voltage of its output by comparing the feedback signal from a resistor divider on the FB pin with an internal 0.6 V reference. When the load current increases, it causes a reduction in the feedback voltage relative to the reference. The error amplifier raises its output voltage until the average inductor current matches the new load current. When the
high side MOSFET turns off, the synchronous power switch (N-MOSFET) turns on until either the bottom current limit is reached or the beginning of the next cycle. The operating frequency is set by the internal oscillator at 1.2MHz. In VIN larger than 6V condition, the high side MOSFET is turned off and the low side MOSFET is switched on until either the VIN over voltage condition is cleared or the low side MOSFET's current limit is reached.
Absolute Maximum Ratings (Note 1)

Note 1. Stresses beyond those listed "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
Note 2. $\theta_{\mathrm{JA}}$ is measured at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ on a high effective thermal conductivity four-layer test board per JEDEC 51-7. $\theta_{\mathrm{Jc}}$ is measured at the exposed pad of the package.
Note 3. Devices are ESD sensitive. Handling precaution is recommended.
Note 4. The device is not guaranteed to function outside its operating conditions..

## Application Information

The RT2652 is a single-phase buck PWM converter. It provides single feedback loop, current mode control with fast transient response. An internal 0.6 V reference allows the output voltage to be precisely regulated for low output voltage applications. A fixed switching frequency ( 1.2 MHz ) oscillator and internal compensation are integrated to minimize external component count.

## Output Voltage Setting

The output voltage is set by an external resistive voltage divider according to the following equation :
$V_{\text {OUT }}=V_{\text {REF }}\left(1+\frac{R 1}{\mathrm{R} 2}\right)$
Where $\mathrm{V}_{\text {REF }}$ is equals 0.6 V (typ.).
The resistive voltage divider allows the FB pin to sense a fraction of the output voltage as shown in Figure 1.

Figure 1. Setting the Output Voltage

## Chip Enable and Disable

The EN pin allows for power sequencing between the controller bias voltage and another voltage rail. The RT2652 remains in shutdown if the EN pin is lower than 400 mV . The recommended EN falling slew rate is faster than $1 \mathrm{~V} /$ $33 \mu \mathrm{~s}$. When the EN pin rises above the $\mathrm{V}_{\text {EN }}$ trip point, the RT2652 begins a new initialization and soft-start cycle.

## Inductor Selection

For a given input and output voltage, the inductor value and operating frequency determine the ripple current. The ripple current $\Delta I_{\mathrm{L}}$ increases with higher $\mathrm{V}_{\mathrm{IN}}$ and decreases with higher inductance.

$$
\Delta \mathrm{L}=\left[\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{f} \times \mathrm{L}}\right] \times\left[1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}\right]
$$

Having a lower ripple current reduces not only the ESR losses in the output capacitors but also the output voltage ripple. Highest efficiency operation is achieved by reducing ripple current at low frequency, but a large inductor is required to attain this goal. For ripple current selection, the value of $\Delta L_{L}=0.4\left(I_{\text {max }}\right)$ is a reasonable starting point. The largest ripple current occurs at the highest $\mathrm{V}_{\mathbb{I}}$. To guarantee that the ripple current stays below a specified maximum value, the inductor should be chosen according to the following equation :
$L=\left[\frac{V_{\text {OUT }}}{f \times \Delta \mathrm{L}(\mathrm{MAX})}\right] \times\left[1-\frac{V_{\text {OUT }}}{\mathrm{VIN}(\mathrm{MAX})}\right]$

## Slope Compensation and Inductor Peak Current

Slope compensation provides stability in constant frequency architectures by preventing sub-harmonic oscillations at duty cycles greater than $50 \%$. It is accomplished internally by adding a compensating ramp to the inductor current signal. Normally, the maximum inductor peak current is reduced when slope compensation is added. In this IC, however, separated inductor current signal is used to monitor over current condition and this keeps the maximum output current relatively constant regardless of duty cycle.

## Low Dropout Operation

The RT2652 is designed to operate down to an input supply voltage of 2.7V. One important consideration at low input supply voltage is that the $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ of the P -Channel and N Channel power switches increases. The user should calculate the power dissipation when the RT2652 is used at $100 \%$ duty cycle with low input voltages to ensure that thermal limits are not exceeded. Slope compensation and inductor peak current slope compensation provides stability in constant frequency architectures by preventing sub-harmonic oscillations at duty cycles greater than $50 \%$.lt is accomplished internally by adding a compensating ramp to the inductor current signal. Normally, the maximum inductor peak current is reduced when slope compensation is added. In the RT2652, however, separated inductor current signals are used to monitor over current condition. This keeps the maximum output current relatively constant regardless of duty cycle.

## Short Circuit Protection

When the output is shorted to ground, the inductor current decays very slowly during a single switching cycle. A current runaway detector is used to monitor inductor current. As current increases beyond the control of current loop, switching cycles will be skipped to prevent current runaway from occurring.

## Under Voltage Lockout Threshold

The IC includes an input Under Voltage Lockout Protection (UVLO). If the input voltage exceeds the UVLO rising threshold voltage, the converter resets and prepares the PWM for operation. If the input voltage falls below the UVLO falling threshold voltage during normal operation, the device stops switching. The UVLO rising and falling threshold voltage includes a hysteresis to prevent noise caused reset.

## Thermal Shutdown

The device implements an internal thermal shutdown function when the junction temperature exceeds $150^{\circ} \mathrm{C}$. The thermal shutdown disables the device until the junction temperature drops below the hysteresis ( $20^{\circ} \mathrm{C}$ typ.). Then, the device is re-enabled and automatically reinstates the power up sequence.

## Thermal Considerations

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula :
$P_{D(M A X)}=\left(T_{J(M A X)}-T_{A}\right) / \theta_{J A}$
where $\mathrm{T}_{J \text { (MAX) }}$ is the maximum junction temperature, $\mathrm{T}_{\mathrm{A}}$ is the ambient temperature, and $\theta_{\mathrm{JA}}$ is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is $125^{\circ} \mathrm{C}$. The junction to ambient thermal resistance, $\theta_{\mathrm{JA}}$, is layout dependent. For WDFN-10L $3 \times 3$ packages, the thermal resistance, $\theta_{\mathrm{JA}}$, is $70^{\circ} \mathrm{C} / \mathrm{W}$ on a standard JEDEC $51-7$ four-layer thermal test
board. The maximum power dissipation at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ can be calculated by the following formulas :
$P_{D(\operatorname{maX})}=\left(125^{\circ} \mathrm{C}-25^{\circ} \mathrm{C}\right) /\left(70^{\circ} \mathrm{C} / \mathrm{W}\right)=1.429 \mathrm{~W}$ for WDFN-10L $3 \times 3$ package

The maximum power dissipation depends on the operating ambient temperature for fixed $\mathrm{T}_{\text {J(MAX) }}$ and thermal resistance, $\theta_{\mathrm{JA}}$. The derating curves in Figure 2 allow the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 2. Derating Curve of Maximum Power Dissipation
