## : ©hipsmall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation, and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

SC104

## POWER MANAGEMENT

## Description

The SC104 is a micro power dc-dc step-up converter which converts an input voltage, in the range of 1.55 V to 10 V , to a constant current. The part features a range of user programmable voltages and currents including dynamic adjustment of the "constant" current. The converter is capable of generating output voltages as low as the input supply voltage and up to 38 V . During shutdown, the part draws a typical 500nA standby current.

The output current is set by the external resistor R1. Dynamic adjustment of the output current can be made by the application of an analog voltage to the ADJ input, or by PWMing this pin.

The peak switch current is programmable through the external resistor $\mathrm{R}_{\text {Lм }}$ enabling the use of a wide range of inductors and battery technologies.

## Features

- Adjustable output current using pulse width modulation or analog voltage input
- 38 V output capability supports up to 10 white LEDs
- Wide range of input voltages 1.55 V to 10 V
- Low quiescent current
- $0.5 \mu \mathrm{~A}$ standby current in shutdown
- Programmable cycle by cycle current limit
- Surface mount packaging ( $3 \times 3 \mathrm{~mm}$ 8pin MLP)
- Output voltage and over-temperature protection

## Applications

- White LED supplies
- Color LED supplies
- Cellular phones
- PDAs
- Electronic books
- Handheld computers
- Wireless web appliances

Typical Application Circuit - 6 LEDs

## POWER MANAGEMENT

Absolute Maximum Ratings
Exceeding the specifications below may result in permanent damage to the device, or device malfunction. Operation outside of the parameters specified in the Electrical Characteristics section is not implied.

| Parameter | Symbol | Maximum | Units |
| :---: | :---: | :---: | :---: |
| Input Supply Voltage | $\mathrm{V}_{\text {IN }}$ | -0.3 to 12 | V |
| LX Pin Voltage (Power switch OFF) | $V_{L X}$ | -0.3 to 55 | V |
| FB Pin Voltage | $V_{\text {FB }}$ | -0.3 to 6 | V |
| EN Pin Voltage | $V_{\text {EN }}$ | -0.3 to 6 | V |
| LIM Pin Voltage | $\mathrm{V}_{\text {LIM }}$ | -0.3 to 6 | V |
| ADJ Pin Voltage | $\mathrm{V}_{\text {ADJ }}$ | -0.3 to 2 | V |

Pin Descriptions

| Pin | Pin Name | Pin Function |
| :---: | :---: | :--- |
| 1 | ADJ | Apply a PWM or analog voltage to this pin for dynamic output current adjustment. |
| 2 | FB | Connects to the resistor in the ground leg of the series LEDs (feedback for the constant load <br> current). |
| 3 | GND | Ground pin. |
| 4 | OUT | Connect to the boost output at the cathode of the schottky diode. This pin is the input for the <br> over-voltage protection circuit. |
| 5 | LX | Internal switch connection. Connect the inductor and the anode of the schottky diode to this pin. |
| 6 | $\mathbb{N}$ | Input supply pin. Connect to a battery or power supply. |
| 7 | LIM | Current limit set pin. A resistor $\left(R_{\text {LIM }}\right)$ connected from LIM to GND sets the peak inductor current <br> limit threshold. |
| 8 | EN | Digital input for enable. Connect this pin to ground for shutdown or connect a voltage between <br> 1.2 V to 5.0 V for enable. A $1 \mathrm{M} \Omega$ pull-up resistor connecting to $\mathbb{N}$ is also acceptable, provided <br> $10 \mu \mathrm{~A}>\mathrm{I}_{\text {EN }}>300$ nA. |

## POWER MANAGEMENT

## Applications Information

## Component Selection - Introduction

Referring to the 6 LED typical schematic below, there are three components that depend upon the application that need to be determined:
RSET - this resistor sets the output current for the device
RLIM - this resistor sets the peak inductor current
L - the output inductor
All the other components can be mostly generalized and are addressed below the following design steps.

## Step 1: Continuous or Discontinuous?

The first thing to do when designing with the SC104 is to determine whether the output inductor will be operating in continuous mode (where the inductor current does not drop to zero while the device is switching) or discontinuous mode (where the inductor current drops to zero while switching). This determination can be made simply by calculating the required duty cycle needed for the target output voltage, and comparing it to the guaranteed minimum value for the maximum duty cycle from the Electrical Characteristics on Page 3. $\%_{\text {DC(MII) }}=70 \%$ (or 0.7 duty). If DC is greater than 0.7 then discontinuous mode is required. The required duty cycle is calculated as follows:
$D C=\frac{\left(V_{\text {OUT }}-V_{\text {IN }}+V_{f}\right)}{\left(V_{\text {OUT }}-V_{\text {CE(SAT) }}+V_{f}\right)}$
Where:
$\mathrm{V}_{\text {out }}=$ output voltage, the sum of the total LED (max.) forward voltage drop at the required output voltage plus the feedback voltage, 0.35 V .
$\mathrm{V}_{\text {IN }}=$ minimum input voltage
$V_{f}=$ Schottky diode (D1) forward voltage drop
$\mathrm{V}_{\mathrm{CE} \text { (SAT) }}=$ power switch saturation voltage
Using the 6 LED example above:
$V_{\text {out }}=(6 * 3.475)+0.35=21.2 \mathrm{~V}$
$V_{\text {IN }}=3 \mathrm{~V}$
$V_{f}=0.35 \mathrm{~V}$
$\mathrm{V}_{\text {CE(SAT) }}=0.25 \mathrm{~V}$
thus $D C=0.87$
Since this value is greater than the guaranteed minimum value for maximum duty cycle, the device will be operating in discontinuous mode to provide the desired output. Note that the duty cycle does not depend upon the output current, and that unless the output to input ratio is low, the device will usually need to be in discontinuous mode, so we will cover that first (Step 1 through Step 5). Continuous mode calculations start at Step 6.

## Step 2: Calculating the Inductor for Discontinuous Mode

Having determined that we need to be operating in discontinuous mode, we next need to calculate the maximum inductor value allowed that will permit the part to output the correct power. The maximum discontinuous inductor value, $\mathrm{L}_{(\mathrm{D})}$ is given by:
$\mathrm{L}_{\text {(D) }}=\frac{\mathrm{t}_{\text {ON(MNN }}{ }^{2} \cdot \mathrm{~V}_{\text {IN }} \cdot\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {CESATT }}\right)}{2 \cdot 1.4 \cdot \mathrm{~V}_{\text {OUT }} \cdot \mathrm{l}_{\text {OUT }} \cdot\left(\mathrm{t}_{\text {ON(MNS) }}+\mathrm{t}_{\text {OFF(MNS) }}\right)} \cdot \frac{\left(\mathrm{V}_{\text {OUT }}-\mathrm{V}_{\text {CE(SAT) }}+\mathrm{V}_{\mathrm{f}}\right)}{\left(\mathrm{V}_{\text {OUT }}-\mathrm{V}_{\text {IN }}+\mathrm{V}_{\mathrm{f}}\right)}$
Where:
$\mathrm{t}_{\mathrm{oN(MIN)}}=$ minimum switch on-time $=1.8 \mu \mathrm{~s}$
$\mathrm{I}_{\text {out }}=$ required output current
$\mathrm{t}_{\text {ofF(MIN) }}=$ minimum switch off-time $=0.6 \mu \mathrm{~s}$
Using our 6 LED example:
$\mathrm{I}_{\text {OUT }}=15 \mathrm{~mA}$
thus $\mathrm{L}_{(\mathrm{D})}=14.4 \mu \mathrm{H}$
Selecting the next lower standard value gives us $\mathrm{L}_{(0)}=12 \mu \mathrm{H}$. Of course a lower value inductor may be used if desired, but may not necessarily be the most efficient choice.

## Step 3: Calculating the Current Limit Required with this Inductor for Discontinuous Mode

Having determined the inductor value we are going to use, we next need to calculate the current limit required to meet the necessary output power. The discontinuous mode current limit, $\mathrm{I}_{\mathrm{LIM(D)}}$, is given by:
$\mathrm{I}_{\text {LIM(D) }}=\frac{\left(\mathrm{V}_{\mathbb{N}_{\mathrm{N}}}-\mathrm{V}_{\text {CE(SAT) }}\right) \cdot \mathrm{t}_{\mathrm{ON(MIN)}}}{\mathrm{~L}_{(\mathrm{D})}}$

## POWER MANAGEMENT

## Applications Information (Cont.)

Step 3: (Cont.)
Using our 6 LED example:
$L_{\text {(D) }}=12 \mu \mathrm{H}$
thus $I_{\text {LIM(D) }}=412 \mathrm{~mA}$

## Step 4: Calculating the Current Limit Resistor for Discontinuous Mode

The current limit resistor value is calculated based upon the minimum ratio of the switch current to the current out of the LIM pin. It also takes into account the fact that there is a propagation delay during which time the inductor current ramps beyond the current limit trip point. Since $I_{\text {LIM }}$ increases as $R_{\text {LIM }}$ decreases, this value is a maximum. The maximum current limit resistor, $\mathrm{R}_{\mathrm{LIM}(\mathrm{D})}$, for discontinuous mode is therefore:

$$
\mathrm{R}_{\mathrm{LIM(D)}}=\frac{\mathrm{V}_{\mathrm{LIM}(\mathrm{MIN})} \bullet \operatorname{Ratio}_{(\mathrm{MIN})}}{\left(\mathrm{L}_{\mathrm{LIM}(\mathrm{D})}-\frac{\mathrm{t}_{\mathrm{plh}} \cdot\left(\mathrm{~V}_{\text {IN }}-\mathrm{V}_{\mathrm{CE}(S A T)}\right)}{\mathrm{L}_{(\mathrm{D})}}\right)}
$$

Where:
$\mathrm{V}_{\text {LIM(MIN) }}=$ the minimum value of the current limit voltage reference $=385 \mathrm{mV}$
Ratio $_{(\text {MII })}=$ the minimum value of the $I_{\mathrm{LX}}$ to $\mathrm{I}_{\text {LIM }}$ ratio $=7100 \mathrm{~A} / \mathrm{A}$
$\mathrm{t}_{\mathrm{plh}}=$ propagation delay from reaching the current limit trip point to the power switch turning off $=200 \mathrm{~ns}$

Using our 6 LED example:
$\mathrm{I}_{\text {LIM(D) }}=412 \mathrm{~mA}$
thus $\mathrm{R}_{\text {LIM(D) }}=7.5 \mathrm{k} \Omega$
Selecting this value or the next lower standard value in this case gives us $7.5 \mathrm{k} \Omega$. Of course a lower value resistor may be used if desired, but may not necessarily be the most efficient choice.

## Step 5: Calculating the Current Set Resistor

The current set resistor is in series with the series LED string. Thus the voltage developed across it is proportional to the current flowing through the LEDs. The device will regulate this voltage so that its average value equals the feedback voltage, $\mathrm{V}_{\mathrm{FB}}$, which is typically 350 mV . Thus the current set resistor value is given by the following
equation:
$R_{S E T}=\frac{V_{F B}}{I_{\text {OUT }}}$
Using our 6 LED example:
$\mathrm{I}_{\text {out }}=15 \mathrm{~mA}$
thus $\mathrm{R}_{\text {SEt }}=23.3 \Omega$
We will select the $1 \%$ resistor value $23.2 \Omega$.
Note: this calculation is applicable to both continuous and discontinuous modes.

## Step 6: Calculating the Inductor for Continuous Mode

Having determined that we need to be operating in continuous mode, we next need to calculate the maximum inductor value allowed that will permit the part to output the correct power. The maximum continuous inductor value, $L_{(c)}$ is given by:
$\mathrm{L}_{\text {(C) }}=\frac{2 \bullet \mathrm{~V}_{\text {IN }} \bullet \mathrm{t}_{\text {OFF(MIN }} \cdot\left(\mathrm{V}_{\text {OUT }}+\mathrm{V}_{\mathrm{f}}-\mathrm{V}_{\text {IN }}\right)}{1.4 \bullet \mathrm{~V}_{\text {OUT }} \bullet \mathrm{l}_{\text {OUT }}}$
Where:
$\mathrm{I}_{\text {out }}=$ required output current
$\mathrm{t}_{\text {off(MIN) }}=$ minimum switch off-time $=0.6 \mu \mathrm{~s}$
Selecting the next lower standard value gives us a safe value for this inductor.

## Step 7: Calculating the Current Limit Required with this Inductor for Continuous Mode

Having determined the inductor value we are going to use, we next need to calculate the current limit required to meet the necessary output power. The continuous mode current limit, $\mathrm{I}_{\text {LIM(C) }}$, is given by:
$\mathrm{I}_{\mathrm{LIM(C)}}=\frac{\left(\mathrm{V}_{\text {OUT }}+\mathrm{V}_{\mathrm{f}}-\mathrm{V}_{\text {IN }}\right) \cdot \mathrm{t}_{\text {OFF(MIN) }}}{0.4 \cdot \mathrm{~L}_{(\mathrm{C})}}$

## Step 8: Calculating the Current Limit Resistor for Continuous Mode

The current limit resistor value is calculated based upon the minimum ratio of the switch current to the current out of the LIM pin. It also takes into account the fact that there is a propagation delay during which time the

## POWER MANAGEMENT

## Applications Information (Cont.)

## Step 8: (Cont.)

inductor current ramps beyond the current limit trip point. Since $I_{\text {LIM }}$ increases as $R_{\text {LIM }}$ decreases, this value is a maximum. The maximum current limit resistor, $\mathrm{R}_{\mathrm{LIMC})}$, for continuous mode is therefore:
$\mathrm{R}_{\mathrm{LIM}(\mathrm{C})}=\frac{\mathrm{V}_{\mathrm{LIM}(\mathrm{MIN})} \bullet \text { Ratio }_{(\text {MIN })}}{\left(\mathrm{L}_{\mathrm{LIM}(\mathrm{C})}-\frac{\mathrm{t}_{\mathrm{plh}} \cdot\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {CE(SAT) }}\right)}{\mathrm{L}_{(\mathrm{C})}}\right)}$
Where:
$\mathrm{V}_{\text {LIM(MIN) }}=$ the minimum value of the current limit voltage reference $=385 \mathrm{mV}$
Ratio $_{\text {(MII) }}=$ the minimum value of the $I_{\text {LX }}$ to $I_{\text {LIM }}$ ratio $=7100 \mathrm{~A} / \mathrm{A}$
$\mathrm{t}_{\mathrm{plh}}=$ propagation delay from reaching the current limit trip point to the power switch turning off $=200 \mathrm{~ns}$

Selecting the calculated value or the next lower standard value is recommended.

## Component Selection - General

Capacitor Selection: the SC104 has been designed to be used with ceramic input and output capacitors. The input to the device should be bypassed using a $4.7 \mu \mathrm{~F}$ ceramic capacitor rated for the maximum input voltage. The output capacitor should be a ceramic capacitor in the range of $0.22 \mu \mathrm{~F}$ to $1 \mu \mathrm{~F}$. Care should be taken that the voltage rating of this capacitor meets the output voltage requriements, and if the part is going to be run open circuit during assembly testing using the OVP feature, then the capacitor should be rated 50 V .

Schottky diode: any schottky diode rated for the average and peak currents being seen in the circuit will suffice. However a higher current rated schottky diode will result in lower forward voltage drops and hence higher efficiency. The selection of the schottky will depend upon the optimum choice between efficiency, board space, and cost.

Inductor: similarly, any inductor rated for the average and peak currents required by the design and capable of operating at the fixed off-time of 760 ns will suffice, but inductors with lower series resistance will result in lower losses. The selection of the inductor will depend upon the optimum choice between efficiency, board space, component height, and cost. Toko D62LCB and D63LCB series work very well.

## LED Dimming

Dimming the LEDs (i.e. reducing the output current from the set level to reduce brightness) can be achieved a couple of ways:

1) PWMing the ADJ pin using an open drain or open collector (with no pull-up). Using a PWM signal at this pin will reduce the output current by alternating between OFF (ADJ $<100 \mathrm{mV}$ ) and switching normally. The lower the duty cycle, the lower the output current. A PWM frequency of 1 kHz maximum is recommended.
2) analog voltage applied to the ADJ pin: apply a DC voltage between OV to 0.1 V (OFF) and 1 V (full current) to the ADJ pin. This pin should not be pulled above 1V under normal operation, and should never exceed the absolute maximum rating. Using a DC voltage will result in the modulation frequency of the inductor current ramp reducing and care must be taken to ensure that this does not become audible in sensitive applications.
