

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## High Speed +5V High Performance RS-232 Transceivers

- Single +5V Supply Operation
- 0.1µF External Charge Pump Capacitors
- 500kbps Data Rate Under Load
- Standard SOIC and SSOP Footprints
- Lower Supply Current Than Competition (typical 3mA)
- 1µA Shutdown Mode
- Wake-Up Feature in Shutdown Mode
- Tri-State Receiver Outputs
- Ideal for High Speed RS-232 Applications
- Improved ESD Specifications:
  - +15kV Human Body Model
  - +15kV IEC 61000-4-2 Air Discharge
  - +8kV IEC 61000-4-2 Contact Discharge

Now Available in Lead Free Packaging

### DESCRIPTION

The **SP211EH/213EH** devices are high speed enhanced multi-channel RS-232 line transceivers with improved electrical performance. The **SP211EH/213EH** series is a superior drop-in replacement to our previous versions as well as popular industry standards. All devices feature very low power CMOS construction and the Exar-patented (5,306,954) on-board charge pump circuitry that generates the +/-10V RS-232 voltage levels using 0.1µF charge pump capacitors. The **SP211EH** and **SP213EH** devices feature a low-power shutdown mode, which reduces power supply drain to 1µA. Enhancements to this series include a higher transmission rate of 500kbps, a lower power supply current at 3mA typical (no load), and superior ESD performance. The ESD tolerance has been improved for this series to over +/-15kV for both Human Body Model and IEC61000-4-2 Air Discharge test methods.

Model	No. of RS-232		No. of Receivers Active in Shutdown	No. of External 0.1µF Capacitors	Shutdown	Wake-Up	TTL Tri-State

## FEATURES

As in the original RS-232 multi-channel products, the **SP211EH** and **SP213EH** high speed multi-channel RS-232 line transceivers provide a variety of configurations to fit most designs, especially high speed applications where +/-12V is not available. The **SP211EH/213EH** is a superior high speed drop-in replacement to our previous versions as well as popular industry standards.

All devices in this series feature low-power CMOS construction and **Exar's** proprietary on-board charge pump circuitry to generate the RS-232 signal voltages. The ability to use 0.1µF charge pump capacitors saves board space and reduces production costs. The devices in this series provide different driver/receiver combinations to match any application requirement.

The **SP211EH** and **SP213EH** models feature a low-power shutdown mode, which reduces power supply drain to 1µA. The **SP213EH** includes a Wake-Up function which keeps two receivers active in the shutdown mode, unless disabled by the EN pin.

The family is available in 28 SOIC (wide) and SSOP (shrink) small outline packages. Devices can be specified for commercial (0°C to +70°C) and industrial/extended (-40°C to +85°C) operating temperatures.

## THEORY OF OPERATION

The **SP211EH** and **SP213EH** devices are made up of three basic circuit blocks — 1) transmitter/driver, 2) receiver and 3) the **EXAR**—proprietary charge pump. Each model within the series incorporates variations of these circuits to achieve the desired configuration and performance.

### Transmitter/Drivers

The drivers of this series can maintain a typical data rate of 500kbps.

This superior RS-232 data transmission rate makes the **SP211EH/213EH** series an ideal match for many designs in personal computer peripherals and LAN applications that demand high speed performance.

The drivers are inverting transmitters, which accept either TTL or CMOS inputs and output the RS-232 signals with an inverted sense relative to the input logic levels. Typically, the RS-232 output voltage swing is +/-9V with no load, and +/-5V minimum with full load. The transmitter outputs are protected against infinite short-circuits to ground without degradation in reliability. The drivers of the **SP211EH**, and **SP213EH** can be tri-stated by using the SHUTDOWN function.

In the "power-off" state, the output impedance will remain greater than 300 ohms, again satisfying the RS-232 specifications. Should the input of the driver be left open, an internal 400k ohm pull-up resistor to V<sub>CC</sub> forces the input high, thus committing the output to a low state. The slew rate of the transmitter output is internally limited to a maximum of 30V/µs in order to meet the EIA/RS-232 and ITU V.28 standards. The transition of the output from high to low also meets the monotonicity requirements of the standard.

### Receivers

The high performance receivers of the **SP211EH/213EH** devices can accept input signals at a typical data rate of 500kbps. The receivers convert RS-232 level input signals to inverted TTL level signals. Since the input is usually from a transmission line where long cable lengths and system interference can degrade the signal, the inputs have a typical hysteresis margin of 500mV. This ensures that the receiver is virtually immune to noisy transmission lines. Should an input be left unconnected, a 5kΩ pull-down resistor to ground will commit the output of the receiver to a high state.

## SHUTDOWN MODE

The **SP211EH** and **SP213EH** both feature a control input which will disable the device and reduce power supply to less than 10 $\mu$ A, making the parts ideal for battery-powered systems. In the "shutdown" mode the receivers and transmitters will both be tri-stated. The V+ output of the charge pump will discharge to Vcc and the V- output will discharge to ground.

For complete shutdown to occur and the 10 $\mu$ A power drain to be realized, the following conditions must be met:

### SP211EH:

- +5V must be applied to the SD pin.
- ENABLE must be either 0V, +5V or not connected
- the transmitter inputs must be either +5.0V or not connected
- Vcc must be +5V
- Receiver inputs must be >0V and <+5V

### SP213EH:

- 0V must be applied top the  $\overline{\text{SD}}$  pin
- ENABLE must be either 0V, +5.0V or not connected
- the transmitter inputs must be either +5.0V or not connected
- Vcc must be +5V
- Receiver inputs must be >0V and <+5V

## ENABLE

**SP211EH** and **SP213EH** feature an enable input, which allows the receiver outputs to be either tri-stated or enabled. This can be especially useful when the receiver is tied directly to a shared microprocessor data bus. For the **SP211EH**, enable is active low; that is, 0V applied to the ENABLE pin will enable the receiver outputs. For the **SP213EH**, enable is active high; that is, +5V applied to the ENABLE pin will enable the receiver outputs.

## WAKE-UP FUNCTION

The **SP213EH** has a wake-up feature that keeps two receivers (R4 and R5) in an enabled state when the device is in shutdown mode. With only the receivers active during shutdown, the devices draw 5-10 $\mu$ A of supply current.

A typical application of this function would be where a modem is interfaced to a computer in a power-down mode. The ring indicator signal from the modem could be passed through an active receiver in the **SP213EH** that is itself in the shutdown mode. The ring indicator signal would propagate through the **SP213EH** to the power management circuitry of the computer to power up the microprocessor and the **SP213EH** drivers. After the supply voltage to the **SP213EH** reaches +5.0V, the SHUTDOWN pin can be disabled, taking the **SP213EH** out of the shutdown mode.

All receivers that are active during shutdown maintain 500mV (typical) of hysteresis.

## Charge-Pump

The charge pump is a **Exar**-patented design (5,306,954) and uses a unique approach compared to older less-efficient designs. The charge pumps still requires four external capacitors, but uses a four-phase voltage shifting technique to attain symmetrical 10V power supplies. Figure 3a shows the waveform found on the positive side of capacitor C<sub>2</sub>, and Figure 3b shows the negative side of capacitor C<sub>2</sub>. There is a free-running oscillator that controls the four phases of the voltage shifting. A description of each phase is as follows:

Figure 5. Typical waveforms seen on capacitor C<sub>2</sub> when all drivers are at maximum load.

### Phase 1

—  $V_{SS}$  charge storage — During this phase of the clock cycle, the positive side of capacitors C<sub>1</sub> and C<sub>2</sub> are initially charged to +5V. C<sub>1</sub><sup>+</sup> is then switched to ground and charge on C<sub>1</sub><sup>+</sup> is transferred to C<sub>2</sub><sup>-</sup>. Since C<sub>2</sub><sup>+</sup> is connected to +5V, the voltage potential across capacitor C<sub>2</sub> is now 10V.

### Phase 2

—  $V_{SS}$  transfer — Phase two of the clock connects the negative terminal of C<sub>2</sub> to the  $V_{SS}$  storage capacitor and the positive terminal of C<sub>2</sub> to ground, and transfers the generated -10V to C<sub>3</sub>. Simultaneously, the positive side of capacitor C<sub>1</sub> is switched to +5V and the negative side is connected to ground.

### Phase 3

—  $V_{DD}$  charge storage — The third phase of the clock is identical to the first phase — the charge transferred in C<sub>1</sub> produces

-5V in the negative terminal of C<sub>1</sub>, which is applied to the negative side of capacitor C<sub>2</sub>. Since C<sub>2</sub><sup>+</sup> is at +5V, the voltage potential across C<sub>2</sub> is 10V.

### Phase 4

—  $V_{DD}$  transfer — The fourth phase of the clock connects the negative terminal of C<sub>2</sub> to ground and transfers the generated 10V across C<sub>2</sub> to C<sub>4</sub>, the  $V_{DD}$  storage capacitor. Again, simultaneously with this, the positive side of capacitor C<sub>1</sub> is switched to +5V and the negative side is connected to ground, and the cycle begins again.

Since both V<sup>+</sup> and V<sup>-</sup> are separately generated from  $V_{CC}$  in a no-load condition, V<sup>+</sup> and V<sup>-</sup> will be symmetrical. Older charge pump approaches that generate V<sup>-</sup> from V<sup>+</sup> will show a decrease in the magnitude of V<sup>-</sup> compared to V<sup>+</sup> due to the inherent inefficiencies in the design.

The clock rate for the charge pump typically operates at 15kHz. The external capacitors must be a minimum of 0.1µF with a 16V breakdown rating.

## ESD TOLERANCE

The **SP211EH/213EH** family incorporates ruggedized ESD cells on all driver output and receiver input pins. The ESD structure is improved over our previous family for more rugged applications and environments sensitive to electro-static discharges and associated transients. The improved ESD tolerance is at least  $\pm 15\text{kV}$  without damage nor latch-up.

There are different methods of ESD testing applied:

- a) MIL-STD-883, Method 3015.7
- b) IEC61000-4-2 Air-Discharge
- c) IEC61000-4-2 Direct Contact

The Human Body Model has been the generally accepted ESD testing method for semiconductors. This method is also specified in MIL-STD-883, Method 3015.7 for ESD testing. The premise of this ESD test is to simulate the human body's potential to store electro-static energy and discharge it to an integrated circuit. The simulation is performed by using a test model as shown in Figure 10. This method will test the IC's capability to withstand an ESD transient during normal handling such as in manufacturing areas where the IC's tend to be handled frequently.

The IEC-61000-4-2, formerly IEC801-2, is generally used for testing ESD on equipment

and systems. For system manufacturers, they must guarantee a certain amount of ESD protection since the system itself is exposed to the outside environment and human presence. The premise with IEC61000-4-2 is that the system is required to withstand an amount of static electricity when ESD is applied to points and surfaces of the equipment that are accessible to personnel during normal usage. The transceiver IC receives most of the ESD current when the ESD source is applied to the connector pins. The test circuit for IEC61000-4-2 is shown on Figure 11. There are two methods within IEC61000-4-2, the Air Discharge method and the Contact Discharge method.

With the Air Discharge Method, an ESD voltage is applied to the equipment under test (EUT) through air. This simulates an electrically charged person ready to connect a cable onto the rear of the system only to find an unpleasant zap just before the person touches the back panel. The high energy potential on the person discharges through an arcing path to the rear panel of the system before he or she even touches the system. This energy, whether discharged directly or through air, is predominantly a function of the discharge current rather than the discharge voltage. Variables with an air discharge such as approach speed of the object carrying the ESD potential to the system and humidity will tend to change the discharge current. For example, the rise time of the discharge current varies with the approach speed.

Figure 10. ESD Test Circuit for Human Body Model

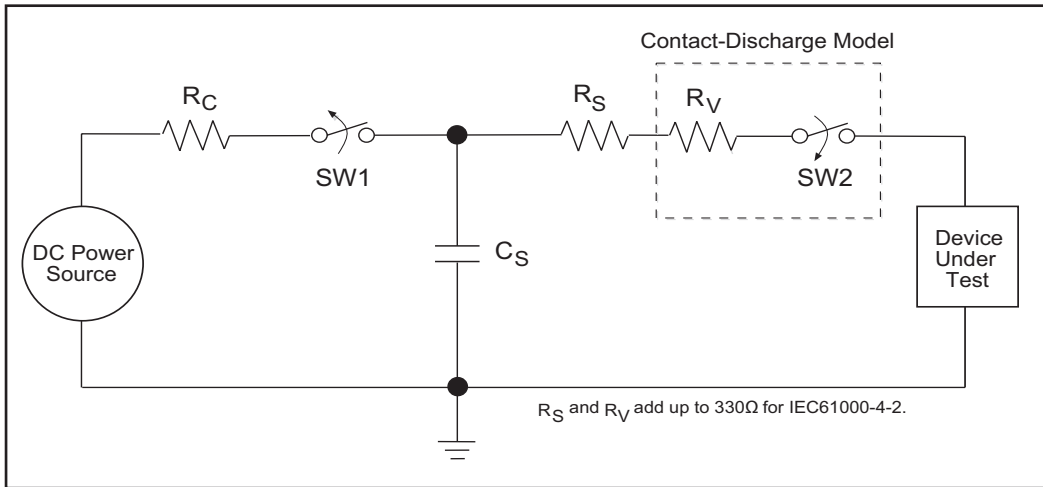

Figure 11. ESD Test Circuit for IEC61000-4-2

The Contact Discharge Method applies the ESD current directly to the EUT. This method was devised to reduce the unpredictability of the ESD arc. The discharge current rise time is constant since the energy is directly transferred without the air-gap arc. In situations such as hand held systems, the ESD charge can be directly discharged to the equipment from a person already holding the equipment. The current is transferred on to the keypad or the serial port of the equipment directly and then travels through the PCB and finally to the IC.

The circuit model in Figures 10 and 11 represent the typical ESD testing circuit used for all three methods. The  $C_S$  is initially charged with the DC power supply when the first switch ( $SW1$ ) is on. Now that the capacitor is charged, the second switch ( $SW2$ ) is on while  $SW1$  switches off. The voltage stored in the capacitor is then applied through  $R_S$ , the current limiting resistor, onto the device under test (DUT). In ESD tests, the  $SW2$  switch is pulsed so that the device under test receives a duration of voltage.

For the Human Body Model, the current limiting resistor ( $R_S$ ) and the source capacitor

Figure 12. ESD Test Waveform for IEC61000-4-2

( $C_S$ ) are 1.5kΩ and 100pF, respectively. For IEC-61000-4-2, the current limiting resistor ( $R_S$ ) and the source capacitor ( $C_S$ ) are 330Ω and 150pF, respectively.

The higher  $C_S$  value and lower  $R_S$  value in the IEC61000-4-2 model are more stringent than the Human Body Model. The larger storage capacitor injects a higher voltage to the test point when  $SW2$  is switched on. The lower current limiting resistor increases the current charge onto the test point.

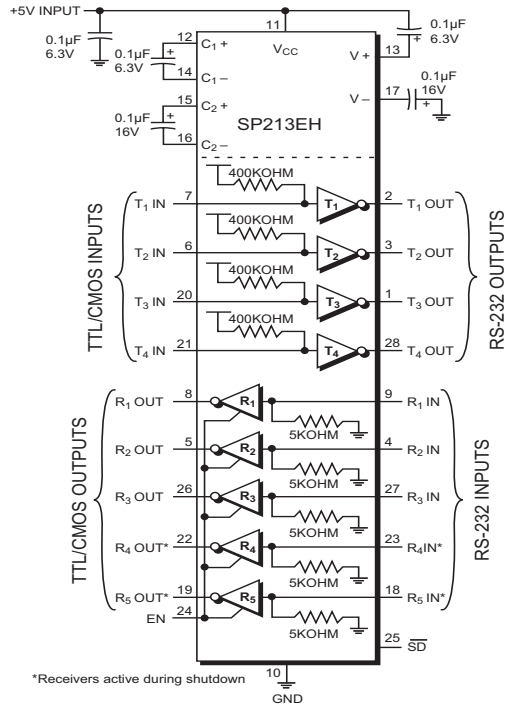

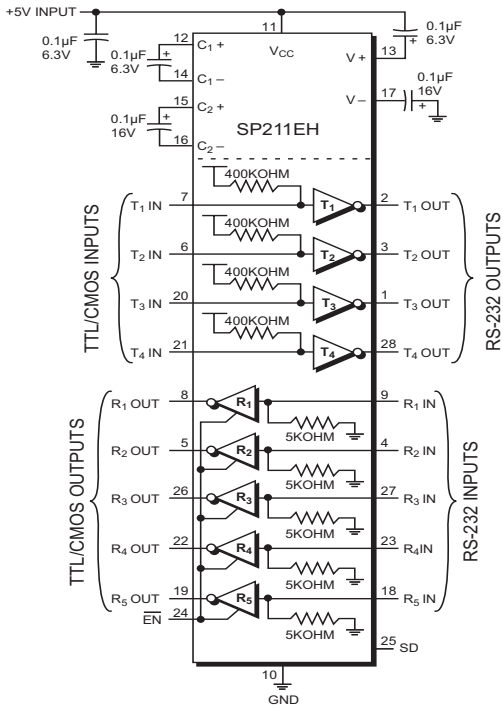

## EIA STANDARDS

The Electronic Industry Association (EIA) developed several standards of data transmission which are revised and updated in order to meet the requirements of the industry. In data processing, there are two basic means of communicating between systems and components. The RS-232 standard was first introduced in 1962 and, since that time, has become an industry standard. The RS-232 is a relatively slow data exchange protocol, with a maximum baud rate of only 20kbps, which can be transmitted over a maximum copper wire cable length of 50 feet. The SP211EH/213EH series of data communications interface products have been designed to meet both the EIA protocol standards, and the needs of the industry.

DEVICE PIN TESTED	HUMAN BODY MODEL	IEC16000-4-2		
		Air Discharge	Direct Contact	Level
Driver Outputs	±15kV	±15kV	±8kV	4
Receiver Inputs	±15kV	±15kV	±8kV	4
