

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

# Low Power Microprocessor Supervisory with Battery Switch-Over

- Precision 4.65V Voltage Monitoring
- 200ms Power-OK/Reset Time Delay
- Independent Watchdog Time-Preset or Adjustable
- 75 $\mu$ A Maximum Operating Supply Current
- 1.0 $\mu$ A Maximum Battery Backup Current
- 0.1 $\mu$ A Maximum Battery Standby Current
- Power Switching
  - 250mA Output in Vcc Mode (0.6 $\Omega$ )
  - 25mA Output in Battery Mode (5 $\Omega$ )
- On-Board Gating of Chip-Enable Signals
  - Memory Write-Cycle Completion
  - 6ns CE Gate Propagation Delay
- Voltage Monitor for Power-Fail or Low Battery
- Backup-Battery Monitor
- $\overline{\text{RESET}}$  Valid to  $V_{\text{CC}}=1\text{V}$
- Pin Compatible Upgrade to MAX791

Now available in Lead Free

## DESCRIPTION

The **SP791** is a microprocessor ( $\mu\text{P}$ ) supervisory circuit that integrates a myriad of components involved in discrete solutions to monitor power-supply and battery-control functions in  $\mu\text{P}$  and digital systems. The **SP791** offers complete  $\mu\text{P}$  monitoring and watchdog functions. The **SP791** is ideal for a low-cost battery management solution and is well suited for portable, battery-powered applications with its supply current of 40 $\mu\text{A}$ . The 6ns chip-enable propagation delay, the 25mA current output in battery-backup mode, and the 250mA current output in standard operation also makes the **SP791** suitable for larger scale, high-performance equipment.

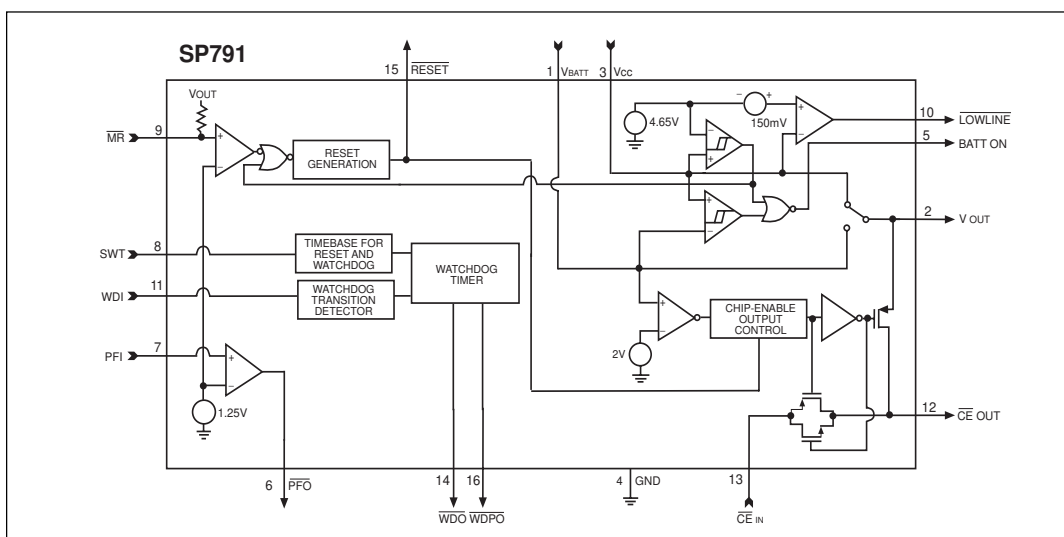

Figure 1. Block Diagram

## ABSOLUTE MAXIMUM RATINGS

Input Voltage (with respect to GND)

VCC.....	-0.3V to +6V
VBATT.....	-0.3V to +6V
All Other Inputs .....	-0.3V to (VOUT + 0.3V)

Input Current

VCC Peak.....	1.0A
VCC Continuous .....	250mA
VBATT Peak .....	250mA
VBATT Continuous.....	25mA
GND, BATT ON .....	100mA
All Other Outputs .....	25mA

Continuous Power Dissipation (TA = +70°C)

Plastic DIP (derate 10.53mW/°C above +70°C)	842mW
Narrow SO (derate 8.70mW/°C above +70°C)	696mW

ESD Rating.....4KV

Stresses beyond these listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Operating Temperature Ranges

SP791C .....	0°C to +70°C
SP791E .....	-40°C to +85°C
Storage Temperature Range.....	-65°C to +160°C
Lead Temperature (soldering, 10sec).....	+300°C

## ELECTRICAL CHARACTERISTICS

(VCC = 4.75V to 5.5V, VBATT = 2.8V, TA = TMIN to TMAX unless otherwise noted, typicals specified at 25°C)

PARAMETER	MIN	TYP	MAX	UNITS	CONDITIONS
Operating Voltage Range VCC, VBATT (Note 1)	0		5.5	V	
VOUT in Normal Operating Mode	VCC - 0.05	VCC - 0.015		V	VCC = 4.5V, IOUT = 25mA
	VCC - 0.3	VCC - 0.15			VCC = 4.5V, IOUT = 250mA
	VCC - 0.2	VCC - 0.09			VCC = 3.0V; VBATT = 2.8V, IOUT = 100mA
VCC-to-VOUT On Resistance		0.6	1.2	Ω	VCC = 4.5V;
		0.9	2.0		VCC = 3.0V;
VOUT in Battery Backup Mode	VBATT - 0.3			V	VBATT = 4.5V, IOUT = 20mA
	VBATT - 0.25				VBATT = 2.8V, IOUT = 10mA
	VBATT - 0.15				VBATT = 2.0V, IOUT = 5mA
VBATT-to-VOUT On Resistance		5	15	Ω	VBATT = 4.5V
		7	25		VBATT = 2.8V
		10	30		VBATT = 2.0V
Supply Current in Normal Operating Mode (Excludes IOUT)		40	75	μA	VCC > VBATT - 1V
Supply Current in Battery Backup Mode (Excludes IOUT) (Note 2)		0.001	1	μA	VCC < VBATT - 1.2V; VBATT = 2.8V
VBATT Standby Current (Note 3)	-0.1		0.02	μA	VBATT + 0.2V < VCC
Battery-Switchover Threshold		VBATT +0.03		V	Power up
		VBATT -0.03			Power down
Battery-Switch over Hysteresis		60		mV	Peak to Peak
Low-Battery Detector Threshold		2		V	

## ELECTRICAL CHARACTERISTICS (continued)

( $V_{CC} = 4.75V$  to  $5.5V$ ,  $V_{BATT} = 2.8V$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$  unless otherwise noted, typicals specified at  $25^\circ C$ )

PARAMETER	MIN	TYP	MAX	UNITS	CONDITIONS
BATT ON Output Low Voltage		0.1	0.4	V	$I_{SINK} = 3.2mA$
		0.7	1.5		$I_{SINK} = 25mA$
BATT ON Output Short Circuit Current		60		mA	Sink Current
	1	15	100	$\mu A$	Source Current
<b>RESET, LOW-LINE AND WATCHDOG TIMER</b>

		55			$V_{OD} = 15mV$
<b>CHIP-ENABLE GATING</b>					
$\overline{CE}$ IN Leakage Current		$\pm 0.005$	$\pm 1$	$\mu A$	Disabled mode
$\overline{CE}$ IN-to- $\overline{CE}$ OUT Resistance (Note 5)		65	150	$\Omega$	Enabled mode
$\overline{CE}$ OUT Short-Circuit Current (Reset Active)	0.1	0.75	2.0	mA	Disabled mode, $\overline{CE}$ OUT = 0V
$\overline{CE}$ IN-to- $\overline{CE}$ OUT Propagation Delay (Note 6)		6	10	ns	50 $\Omega$ source impedance driver, $C_{LOAD} = 50pF$
$\overline{CE}$ OUT Output Voltage High (Reset Active)	3.5			V	$V_{CC} = 5V$ , $I_{OUT} = 100\mu A$
	2.7				$V_{CC} = 0V$ , $V_{BATT} = 2.8V$ , $I_{OUT} = 1\mu A$
$\overline{RESET}$ -to- $\overline{CE}$ OUT Delay		15		$\mu s$	Power down
<b>MANUAL RESET INPUT</b>					
$\overline{MR}$ Minimum Pulse Width	25	15		$\mu s$	
$\overline{MR}$ -to- $\overline{RESET}$ Propagation Delay		7		$\mu s$	
$\overline{MR}$ Threshold		1.25		V	$V_{CC} = 5V$
$\overline{MR}$ Pull-Up Current		23	250	$\mu A$	$\overline{MR} = 0V$

**Note 1:** Either  $V_{CC}$  or  $V_{BATT}$  can go to 0V, if the other is greater than 2.0V.

**Note 2:** The supply current drawn by the SP791 from the battery (excluding  $I_{OUT}$ ) typically goes to 10 $\mu A$  when  $(V_{BATT} - 1V) < V_{CC} < V_{BATT}$ . In most applications, this is a brief period as  $V_{CC}$  falls through this region.

**Note 3:** "+" = battery-discharging current, "-" = battery-charging current.

**Note 4:** WDI is internally connected to a voltage divider between  $V_{OUT}$  and GND. If unconnected, WDI is driven to 1.6V (typ), disabling the watchdog function.

**Note 5:** The chip-enable resistance is tested with  $V_{CC} = 4.75V$  ::  $V_{CE IN} = V_{CE OUT} = V_{CC}/2$ .

**Note 6:** The chip-enable propagation delay is measured from the 50% point at  $\overline{CE}$  IN to the 50% point at  $\overline{CE}$  OUT.

## PINOUT

## PIN ASSIGNMENTS

Pin 1 —  $V_{BATT}$  — Backup-Battery Input. Connect to external battery or capacitor and charging circuit.

Pin 2 —  $V_{OUT}$  — Output Supply Voltage.  $V_{OUT}$  connects to  $V_{CC}$  when  $V_{CC}$  is greater than  $V_{BATT}$  and  $V_{CC}$  is above the reset threshold. When  $V_{CC}$  falls below  $V_{BATT}$  and  $V_{CC}$  is below the reset threshold,  $V_{OUT}$  connects to  $V_{BATT}$ . Connect a 0.1 $\mu$ F capacitor from  $V_{OUT}$  to GND.

Pin 3 —  $V_{CC}$  — Input Supply Voltage — +5V input

Pin 4 — GND — Ground reference for all signals

Pin 5 — BATT ON — Battery On Output. Goes high when  $V_{OUT}$  switches to  $V_{BATT}$ . Goes low when  $V_{OUT}$  switches to  $V_{CC}$ . Connect the base of a PNP through a current-limiting resistor to BATT ON for  $V_{OUT}$  current requirements greater than 250mA.

Pin 6 — PFO — Power-Fail Output. This is the output of the power-fail comparator. PFO goes low when PFI is less than 1.25V. This is an uncommitted comparator, and has no effect on any other internal circuitry.

Pin 7 — PFI — Power-Fail Input. This is the noninverting input to the power-fail comparator. When PFI is less than 1.25V, PFO goes low. Connect PFI to GND or  $V_{OUT}$  when not used.

Pin 8 — SWT — Set Watchdog-Timeout Input. Connect this input to  $V_{OUT}$  to select the default 1.6 sec watchdog timeout period. Connect a capacitor between this input and GND

to select another watchdog-timeout period. Watchdog-timeout period = 2.1 x (capacitor value in nF) ms.

Pin 9 —  $\overline{MR}$  — Manual-Reset Input. This input can be tied to an external momentary pushbutton switch, or to a logic gate output.  $\overline{RESET}$  remains low as long as  $\overline{MR}$  is held low and for 200ms after  $\overline{MR}$  returns high.

Pin 10 —  $\overline{LOWLINE}$  —  $\overline{LOWLINE}$  Output goes low when  $V_{CC}$  falls to 150mV above the reset threshold. The output can be used to generate an NMI (nonmaskable interrupt) if the unregulated supply is inaccessible.

Pin 11 — WDI — Watchdog Input. WDI is a three-level input. If WDI remains either high or low for longer than the watchdog timeout period,  $\overline{WDO}$  goes low.  $\overline{WDO}$  remains low until the next transition at WDI. Leaving WDI unconnected disables the watchdog function. WDI connects to an internal voltage divider between  $V_{OUT}$  and GND, which sets it to mid-supply when left unconnected.

Pin 12 —  $\overline{CE OUT}$  — Chip-Enable Output.  $\overline{CE OUT}$  goes low only when  $\overline{CE IN}$  is low and  $V_{CC}$  is above the reset threshold. If  $\overline{CE IN}$  is low when reset is asserted,  $\overline{CE OUT}$  will stay low for 15 $\mu$ s or until  $\overline{CE IN}$  goes high, whichever occurs first.

Pin 13 —  $\overline{CE IN}$  — Chip-Enable Input. The Input to chip-enable gating circuit. Connect to GND or  $V_{OUT}$  if not used.

Pin 14 —  $\overline{WDO}$  — Watchdog Output.  $\overline{WDO}$  goes low if WDI remains either high or low longer than the watchdog timeout period.  $\overline{WDO}$  returns high on the next transition at WDI.  $\overline{WDO}$  remains high if WDI is unconnected.  $\overline{WDO}$  is also high when  $\overline{RESET}$  is asserted.

Pin 15 —  $\overline{RESET}$  —  $\overline{RESET}$  Output goes low whenever  $V_{CC}$  falls below the reset threshold.  $\overline{RESET}$  will remain low for 200ms after  $V_{CC}$  crosses the reset threshold on power-up.

Pin 16 —  $\overline{WDPO}$  — Watchdog-Pulse Output. Upon the absence of a transition at WDI,  $\overline{WDPO}$  will pulse low for a minimum of 1ms.  $\overline{WDPO}$  precedes  $\overline{WDO}$  by 70ns.

## FEATURES

The **SP791** is a microprocessor ( $\mu\text{P}$ ) supervisory circuit that monitors the power supplied to digital circuits such as microprocessors, microcontrollers, or memory. The **SP791** is an ideal solution for portable, battery-powered equipment that require power supply monitoring. The **SP791** watchdog functions will continuously oversee the operational status of a system. Implementing the **SP791** will reduce the number of components and overall complexity in a design that requires power supply monitoring circuitry. The operational features and benefits of the **SP791** are described in more detail below.

## THEORY OF OPERATION

The **SP791** is a complete  $\mu\text{P}$  supervisor IC and provides the following main functions:

- 1)  $\mu\text{P}$  reset  $\Rightarrow$   $\overline{\text{RESET}}$  output is asserted during power fluctuations such as power-up, power-down, and brown out conditions, and is guaranteed to be in the correct state for  $V_{\text{CC}}$  down to 1V.

Figure 3. Diode "OR" connections allow multiple reset sources to connect to MR.

- 2) Manual-Reset input  $\Rightarrow$  Manually resets RESET output
- 3) Power Fail Comparator  $\Rightarrow$  Provides for power-fail warning and low-battery detection, or monitors another power supply.
- 4) Watchdog function  $\Rightarrow$  Monitors  $\mu\text{P}$  activity where the watchdog output goes to a logic LOW state if the watchdog input is not toggled for a period greater than the timeout period.
- 5) Internal switch  $\Rightarrow$  Switches over from  $V_{\text{CC}}$  to  $V_{\text{BATT}}$  if the  $V_{\text{CC}}$  falls below the reset threshold and below  $V_{\text{BATT}}$ .

## MANUAL RESET INPUT

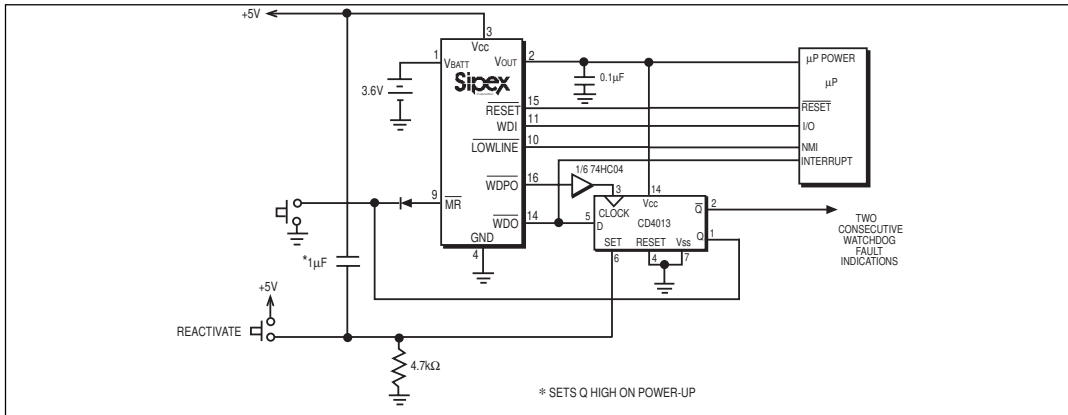

Many microprocessor or microcontroller products include manual-reset capability, allowing the operator or test technician to initiate a reset. The Manual Reset Input ( $\overline{\text{MR}}$ ) can be connected directly to a switch, without an external pull-up resistor. It connects to a 1.25V comparator, and has an internal pull-up to  $V_{\text{OUT}}$  as shown in *Figure 1*. The propagation delay from asserting  $\overline{\text{MR}}$  to  $\overline{\text{RESET}}$  being asserted is 7 $\mu\text{s}$  typical. Pulsing

**Figure 4.** Adding an external pull-down resistor ensures  $\overline{\text{RESET}}$  is valid with  $V_{CC}$  down to  $\text{GND}$ .

**Figure 5.**  $\overline{\text{WDI}}$ ,  $\overline{\text{WDO}}$  and  $\overline{\text{WDPO}}$  Timing Diagram ( $V_{CC}$  mode).

**Figure 6.** Two consecutive watchdog faults latch the system in reset.

$\overline{\text{MR}}$  low for a minimum of  $25\mu\text{s}$  resets all the internal counters, sets the Watchdog Output ( $\overline{\text{WDO}}$ ) and Watchdog-Pulse Output ( $\overline{\text{WDPO}}$ ) high, and sets the Set Watchdog-Timeout (SWT) input to  $\text{VOUT}$  if it is not already connected to  $\text{VOUT}$  (for Internal timeouts). It also, disables the Chip-Enable Output ( $\overline{\text{CE OUT}}$ ) forcing it to a high state. The  $\overline{\text{RESET}}$  output remains at a logic low as long as  $\overline{\text{MR}}$  is held low, and the reset-timeout period begins after  $\overline{\text{MR}}$  returns high, *Figure 2*.

Use this input as either a digital-logic input or a second low-line comparator. Normal TTL/CMOS levels can be wire-OR connected via pull-down diodes, *Figure 3*, and open-drain/collector outputs can be wire-ORed directly.

### RESET OUTPUT

The **SP791**'s  $\overline{\text{RESET}}$  output ensures that the  $\mu\text{P}$  powers up in a known state, and prevents code-execution errors during power-down or brown-out conditions.

The  $\overline{\text{RESET}}$  output is active low, and typically sinks  $3.2\text{mA}$  at  $0.1\text{V}$  saturation voltage in its active state. When deasserted,  $\overline{\text{RESET}}$  sources

$1.6\text{mA}$  at  $\text{VOUT} - 0.5\text{V}$ . When no backup battery is used,  $\overline{\text{RESET}}$  output is valid down to  $V_{CC} = 1\text{V}$ , and an external  $10\text{k}\Omega$  pull-down resistor on  $\overline{\text{RESET}}$  ensures that  $\overline{\text{RESET}}$  will be valid with  $V_{CC}$  down to  $\text{GND}$  as shown on *Figure 4*. As  $V_{CC}$  goes below  $1\text{V}$ , the gate drive to the  $\overline{\text{RESET}}$  output switch reduces accordingly, increasing the  $r_{DS(ON)}$  and the saturation voltage. The  $10\text{k}\Omega$  pull-down resistor ensures the parallel combination of switch and external resistor is  $10\text{k}\Omega$  and the output saturation voltage is below  $0.4\text{V}$ , while sinking  $40\mu\text{A}$ . When using a  $10\text{k}\Omega$  external pull-down resistor, the high state for the  $\overline{\text{RESET}}$  output with  $V_{CC} = 4.75\text{V}$  is  $4.5\text{V}$  typical. For battery voltages greater than or equal to  $2\text{V}$ ,  $\overline{\text{RESET}}$  remains valid for  $V_{CC}$  between  $0\text{V}$  and  $5.5\text{V}$ .  $\overline{\text{RESET}}$  will be asserted during the following conditions:

- 1)  $V_{CC} < 4.65\text{V}$  (typ)
- 2)  $\overline{\text{MR}} < 1.25\text{V}$  (typ)
- 3)  $\overline{\text{RESET}} = \text{logic "0"}$  ; for  $200\text{ms}$  (typ) after  $V_{CC}$  rises above  $4.65\text{V}$  or after  $\overline{\text{MR}}$  has exceeded  $1.25\text{V}$ .

The **SP791** battery-switchover comparator does not affect  $\overline{\text{RESET}}$  assertion.

## WATCHDOG FUNCTION

The watchdog monitors  $\mu\text{P}$  activity via the Watchdog Input (WDI). If the  $\mu\text{P}$  becomes inactive over a period of time,  $\overline{\text{WDO}}$  and  $\overline{\text{WDPO}}$  are asserted.

To use the watchdog function, connect WDI to a bus line or  $\mu\text{P}$  I/O line. If WDI remains high or low for longer than the watchdog timeout period (1.6sec nominal),  $\overline{\text{WDPO}}$  and  $\overline{\text{WDO}}$  are asserted, indicating a software fault or idle condition.

## WATCHDOG INPUT

A change of logic state (minimum 100ns duration) at WDI during the watchdog period will reset the watchdog timer. The watchdog default timeout is 1.6sec. To select an alternative timeout period, connect an external capacitor from SWT to GND.

To disable the watchdog function, leave WDI floating. An internal impedance network (100k $\Omega$  equivalent at WDI) biases WDI to approximately 1.6V. Internal comparators detect this level and disable the watchdog timer. When Vcc is below the reset threshold, the watchdog function is disabled and WDI is disconnected from its internal network, thus becoming high impedance.

## WATCHDOG OUTPUT

$\overline{\text{WDO}}$  remains high if there is activity (transition or pulse) at WDI during the watchdog-timeout period. The watchdog function is disabled and  $\overline{\text{WDO}}$  is a logic high when VCC is less than the reset threshold, or when WDI is an open circuit. In watchdog mode, if no transition occurs at WDI during the watchdog-timeout period,  $\overline{\text{WDO}}$  goes low 70ns after the falling edge of  $\overline{\text{WDPO}}$  and remains low until the next transition at WDI as shown on *Figure 5*. A flip-flop can force the system into a hardware shutdown if there are two successive watchdog faults, shown on *Figure 6*.  $\overline{\text{WDO}}$  has a 2 x TTL output characteristic.

## WATCHDOG-PULSE OUTPUT

As described in the preceding section,  $\overline{\text{WDPO}}$  can be used as the clock input to an external D flip-flop. Upon the absence of a watchdog edge or pulse at WDI at the end of a watchdog-timeout period,  $\overline{\text{WDPO}}$  will pulse low for 1ms. The fall-

ing edge of  $\overline{\text{WDPO}}$  precedes  $\overline{\text{WDO}}$  by 70ns. Since  $\overline{\text{WDO}}$  is high when  $\overline{\text{WDPO}}$  goes low, the Q output of the flip-flop remains high as  $\overline{\text{WDO}}$  goes low (*Figure 6*). If the watchdog timer is not reset by a transition at WDI,  $\overline{\text{WDO}}$  remains low and  $\overline{\text{WDPO}}$  clocks a logic low to the Q output, causing the **SP791** to latch in reset. If the watchdog timer is reset by a transition at WDI,  $\overline{\text{WDO}}$  goes high and the flip-flop's Q output remains high. Thus, a system shutdown is only caused by two successive watchdog faults.

The internal pull-up resistors associated with  $\overline{\text{WDO}}$  and  $\overline{\text{WDPO}}$  connect to VOUT. Therefore, do not connect these outputs directly to CMOS logic that is powered from VCC since, in the absence of VCC (i.e., battery mode), excessive current will flow from  $\overline{\text{WDO}}$  or  $\overline{\text{WDPO}}$  through the protection diode(s) of the CMOS-logic inputs to ground.

## SELECTING AN ALTERNATIVE WATCHDOG TIMEOUT PERIOD

SWT input controls the watchdog-timeout period. Connecting SWT to VOUT selects the internal 1.6sec watchdog-timeout period. Select an alternative timeout period by connecting a capacitor between SWT and GND. Do not leave SWT floating, and do not connect it to ground. The following formula determines the watchdog-timeout period:

$$\text{Watchdog Timeout Period} = 2.1 \times (\text{capacitor value in nF}) \text{ ms}$$

This formula is valid for capacitance values between 4.7 nF and 100nF (see the Watchdog Timeout vs. Timing Capacitor graph in the *Typical Operating Characteristics*).

## CHIP-ENABLE SIGNAL GATING

The **SP791** provides internal gating of chip-enable (CE) signals to prevent erroneous data from corrupting the CMOS RAM in the event of a power failure. During normal operation, the CE gate is enabled and passes all CE transitions. When reset is asserted, this path becomes disabled, preventing erroneous data from corrupting the CMOS RAM. The **SP791** uses a series transmission gate from  $\overline{\text{CE}}$  IN to  $\overline{\text{CE}}$  OUT.

Figure 7. Reset and Chip-Enable Timing

The 10ns maximum  $\overline{CE}$  propagation from  $\overline{CE}$  IN to  $\overline{CE}$  OUT enables the **SP791** to be used with most  $\mu$ Ps.

### CHIP-ENABLE INPUT

$\overline{CE}$  IN is high impedance (disabled mode) while  $\overline{RESET}$  is asserted.

During a power-down sequence where  $V_{CC}$  falls below 4.65V,  $\overline{CE}$  IN assumes a high impedance state when the voltage at  $\overline{CE}$  IN goes high or 15 $\mu$ s after  $\overline{RESET}$  is asserted, whichever occurs first, (Figure 7).

During a power-up sequence,  $\overline{CE}$  IN remains high impedance until  $\overline{RESET}$  is deasserted.

In the high-impedance mode, the leakage currents into this input are less than 1 $\mu$ A over temperature. In the low-impedance mode, the impedance of  $\overline{CE}$  IN appears as a 65 $\Omega$  resistor in series with the load at  $\overline{CE}$  OUT.

The propagation delay through the  $\overline{CE}$  transmission gate depends on both the source impedance of the drive to  $\overline{CE}$  IN and the capacitive loading on  $\overline{CE}$  OUT (see the Chip-Enable Propagation Delay vs.  $\overline{CE}$  OUT Load

Capacitance graph in the *Typical Operating Characteristics*). The  $\overline{CE}$  propagation delay is defined from the 50% point on  $\overline{CE}$  IN to the 50% point on  $\overline{CE}$  OUT using a 50 $\Omega$  driver with 50pF load capacitance as in Figure 8. For minimum propagation delay, minimize the capacitive load at  $\overline{CE}$  OUT and use a low output-impedance driver.

### CHIP-ENABLE OUTPUT

In the enabled mode, the impedance of  $\overline{CE}$  OUT is equivalent to 65 $\Omega$  in series with the source driving  $\overline{CE}$  IN. In the disabled mode, the 65 $\Omega$  transmission gate is off and  $\overline{CE}$  OUT is actively pulled to  $V_{OUT}$ . This source turns off when the transmission gate is enabled.

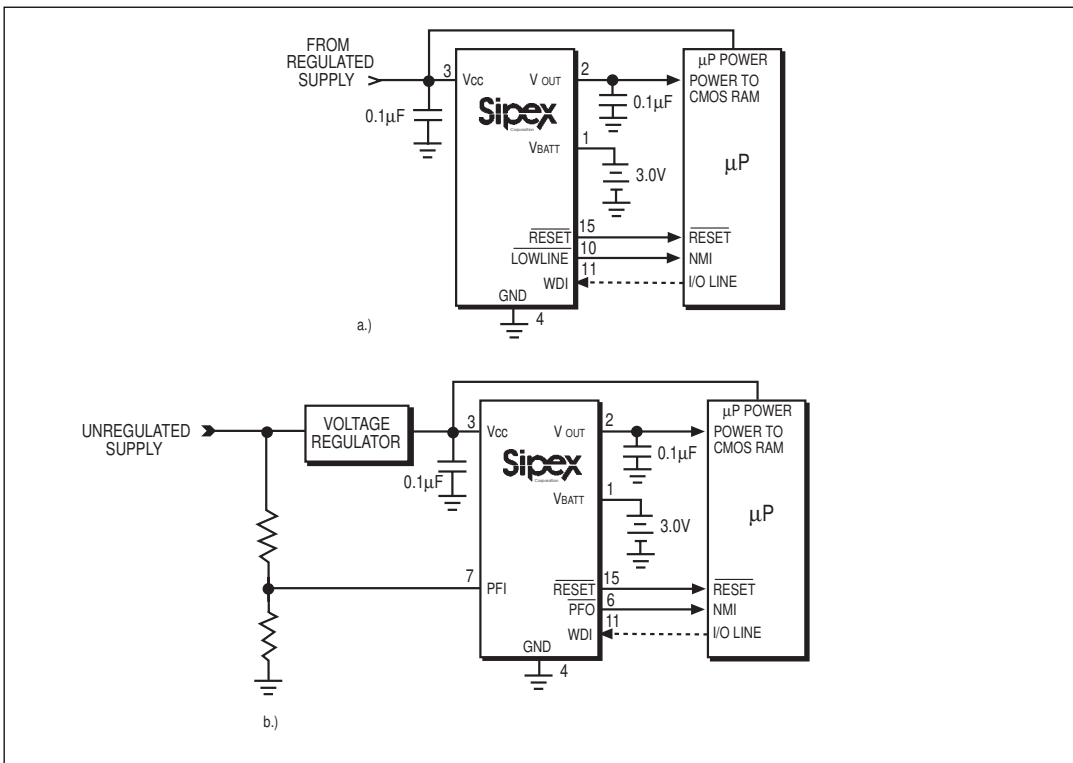

Figure 8. CE Propagation Delay Test Circuit

**Figure 9.** a) If the unregulated supply is inaccessible, **LOWLINE** generates the **NMI** for the  $\mu\text{P}$ .  
b) Use **PFO** to generate the  $\mu\text{P}$  **NMI** if the unregulated supply is accessible.

## LOWLINE OUTPUT

The low-line comparator monitors  $V_{CC}$  with a typical threshold voltage 150mV above the reset threshold and has 15mV of hysteresis. **LOWLINE** typically sinks 3.2mA at 0.1V. For normal operation ( $V_{CC}$  above the **LOWLINE** threshold), **LOWLINE** is pulled to  $V_{OUT}$ . If access to the unregulated supply is unavailable, use **LOWLINE** to provide a nonmaskable interrupt (NMI) to the  $\mu\text{P}$  as shown in *Figure 9a*.

## POWER-FAIL COMPARATOR

The power-fail comparator is an uncommitted comparator that has no effect on the other functions of the **SP791**. Common uses include monitoring supplies other than 5V (see the *Typical Operating Circuit* and the *Monitoring a Negative Voltage* section) and early power-fail detection when the unregulated power is easily accessible as shown in *Figure 9b*.

## POWER-FAIL INPUT

The Power-Fail Input (PFI) has a guaranteed input leakage of  $\pm 25\text{nA}$  max over temperature. The typical comparator delay is 15 $\mu\text{s}$  from  $V_{IL}$  to  $V_{OL}$  (power failing), and 55 $\mu\text{s}$  from  $V_{IH}$  to  $V_{OH}$  (power being restored). Connect PFI to ground if not used.

## POWER-FAIL OUTPUT

The Power-Fail Output (**PFO**) goes low when PFI falls below 1.25V. It sinks 3.2mA with a saturation voltage of 0.1V. With PFI above 1.25V, **PFO** is actively pulled to  $V_{OUT}$ . Connecting PFI through a voltage divider to an unregulated supply allows **PFO** to generate an NMI as the unregulated power begins to fall (see *Figure 9b*).

## INPUT/OUTPUT STATES IN BATTERY-BACKUP MODE

PIN	NAME	STATUS
1	V <sub>BATT</sub>	Supply current is 1μA maximum When $V_{CC} < V_{BATT} - 1.2V$
2	V <sub>OUT</sub>	V <sub>OUT</sub> is connected to V <sub>BATT</sub> through an Internal PMOS switch.
3	V <sub>CC</sub>	Battery-switchover comparator monitors V <sub>CC</sub> for active switchover. V <sub>CC</sub> is disconnected from V <sub>OUT</sub> .
4	GND	GND-0V reference for all signals.
5	BATT ON	Logic high. The open-circuit output is equal to V <sub>OUT</sub> .
6	PFO	The power-fail comparator is disabled PFO is forced low.
7	PFI	The power-fail comparator is disabled
8	SWT	SWT is Ignored.
9	MR	MR is ignored.
10	LOWLINE	Logic low.
11	WDI	WDI is ignored, and goes high impedance.
12	CE <sub>OUT</sub>	Logic high. The open-circuit output voltage is equal to V <sub>OUT</sub> .
13	CE <sub>IN</sub>	High Impedance.
14	WDO	Logic high. The open-circuit output voltage is equal to V <sub>OUT</sub> .
15	RESET	Logic low.
16	WDPO	Logic high. The open-circuit output voltage is equal to V <sub>OUT</sub> .

**Table 1. Input/Output states in Battery-Backup mode**

To enter the Battery-Backup mode, V<sub>CC</sub> must be less than the Reset threshold and less than V<sub>BATT</sub>.

### BATTERY-BACKUP MODE

The SP791 requires two conditions to switch to battery-backup mode: 1) V<sub>CC</sub> must be below the reset threshold; 2) V<sub>CC</sub> must be below V<sub>BATT</sub>. Table 1 lists the status of the inputs and outputs in battery-backup mode.

### BATTERY ON OUTPUT

The Battery On Output (BATT ON) indicates the status of the internal V<sub>CC</sub>/battery-switchover comparator, which controls the internal V<sub>CC</sub> and V<sub>BATT</sub> switches. For V<sub>CC</sub> greater than V<sub>BATT</sub> (ignoring the small hysteresis effect), BATT ON is a logic low. For V<sub>CC</sub> less than V<sub>BATT</sub>, BATT ON is a logic high. Use BATT ON to indicate battery-switchover status or to supply base drive to an external pass transistor for higher-current applications (see *Typical Operating Circuit*).

**Figure 10. V<sub>CC</sub> and V<sub>BATT</sub>-to-V<sub>OUT</sub> Switch**

### INPUT SUPPLY VOLTAGE

The Input Supply Voltage (V<sub>CC</sub>) should be a regulated +5V source. V<sub>CC</sub> connects to V<sub>OUT</sub> via a parallel diode and a large PMOS switch (Figure 10). The switch carries the entire current load for currents less than 250mA. The parallel diode carries any current in excess of 250mA. The maximum continuous current is 250mA, but power-on transients may reach a maximum of 1A.

### BACKUP-BATTERY INPUT

The Backup-Battery Input (V<sub>BATT</sub>) is similar to V<sub>CC</sub>, except the PMOS switch and parallel diode are much smaller. Continuous current should be limited to 25mA and peak currents (only during power-up) limited to 250mA. The reverse leakage of this input is less than 1μA over temperature and supply voltage.

### OUTPUT SUPPLY VOLTAGE

The Output Supply Voltage (V<sub>OUT</sub>) supplies all the current to the external system and internal circuitry. All open-circuit outputs will, for example, assume the V<sub>OUT</sub> voltage in their high states rather than the V<sub>CC</sub> voltage. At the maximum source current of 250mA, V<sub>OUT</sub> will typically be 200mV below V<sub>CC</sub>. V<sub>OUT</sub> should be decoupled with 0.1μF capacitor.

Figure 11. Backup-Battery Monitor Timing Diagram

## LOW-BATTERY MONITOR

The **SP791** low-battery voltage function monitors  $V_{BATT}$ . Low-battery detection of  $2.0V \pm 0.15V$  is monitored only during the reset-timeout period (200ms) that occurs either after a normal power-up sequence or after the  $\overline{MR}$  reset input has been returned to its high state. If the battery voltage is below 2.0V, the second CE pulse is inhibited after reset timeout. If the battery voltage is above 2.0V, all CE pulses are allowed through the CE gate after the reset timeout period. To use this function, after the 200ms reset delay, write 00 (HEX) to a location using the first CE pulse, and write FF (HEX) to the same location using the second CE pulse following  $\overline{RESET}$  going inactive on power-up. The contents of the memory then indicates a good battery (FF) or a low battery (00), *Figure 11*.

## TYPICAL APPLICATIONS

The **SP791** is not short-circuit protected. Shorting  $V_{OUT}$  to ground, other than power-up transients such as charging a decoupling capacitor, may destroy the device. All open-circuit outputs swing between  $V_{OUT}$  and GND rather than  $V_{CC}$  and GND. If long leads connect to the chip inputs, ensure that these lines are free from ringing and other conditions that would forward bias the chip's protection diodes.

Figure 12. High Capacity Capacitor on  $V_{BATT}$

There are three distinct modes of operation:

- 1) Normal operating mode with all circuitry powered up from  $V_{CC}$ . Typical supply current from  $V_{CC}$  is  $40\mu A$ , while only leakage currents flow from the battery.
- 2) Battery-backup mode where  $V_{CC}$  is typically within 0.7V below  $V_{BATT}$ . All circuitry is powered up from  $V_{BATT}$ , and the supply current is typically less than  $40\mu A$ .
- 3) Battery-backup mode where  $V_{CC}$  is less than  $V_{BATT}$  by at least 0.7V.  $V_{BATT}$  supply current is less than  $1\mu A$ .

## USING HIGH CAPACITY CAPACITOR WITH THE SP791

$V_{BATT}$  has the same operating voltage range as  $V_{CC}$ , and the battery-switchover threshold voltages are typically +30mV centered at  $V_{BATT}$ , allowing use of a capacitor and a simple charging circuit as a backup source (see *Figure 12*).

If  $V_{CC}$  is above the reset threshold and  $V_{BATT}$  is 0.5V above  $V_{CC}$ , current flows to  $V_{OUT}$  and  $V_{CC}$  from  $V_{BATT}$  until the voltage at  $V_{BATT}$  is less than 0.5V above  $V_{CC}$ .

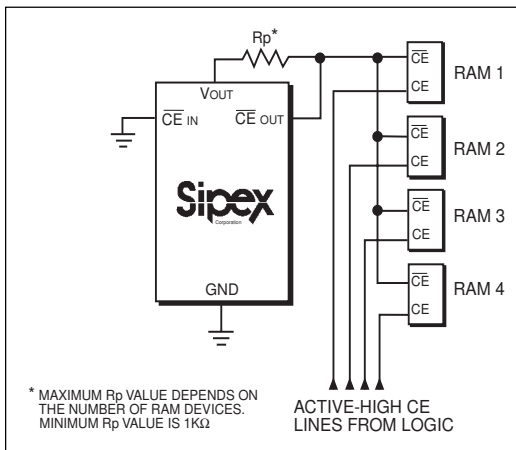

Figure 13. Alternate CE Gating

Leakage current through the capacitor charging diode and the SP791 internal power diode eventually discharges the capacitor to VCC. Also, if VCC and VBATT start from 0.5V above the reset threshold and power is lost at VCC, the capacitor on VBATT discharges through VCC until VBATT reaches the reset threshold; the SP791 then switches to battery-backup mode.

### USING SEPARATE POWER SUPPLIES FOR VBATT AND VCC

If using separate power supplies for VCC and VBATT, VBATT must be less than 0.3V above VCC when VCC is above the reset threshold. As described in the previous section, if VBATT exceeds this limit and power is lost at VCC, current flows continuously from VBATT to VCC via the VBATT-to-VOUT diode and the VOUT-to-VCC switch until the circuit is broken.

### ALTERNATIVE CHIP-ENABLE GATING

Using memory devices with  $\overline{CE}$  and  $\overline{CE}$  inputs allows the SP791 CE loop to be bypassed. To do this, connect  $\overline{CE}$  IN to ground, pull up  $\overline{CE}$  OUT to VOUT, and connect  $\overline{CE}$  OUT to the  $\overline{CE}$  input of each memory device as shown in Figure 13. The  $\overline{CE}$  input of each part then connects directly to the chip-select logic, which does not have to be gated by the SP791.

Figure 14. Adding Hysteresis to the Power-Fail Comparator

### ADDING HYSTERESIS TO THE POWER-FAIL COMPARATOR

Hysteresis adds a noise margin to the power-fail comparator and prevents repeated triggering of PFO when VIN is near the trip point. Figure 14 shows how to add hysteresis to the power-fail comparator. Select the ratio of R1 to R2 such that PFI sees 1.25V when VIN falls to the desired trip point (VTRIP). Resistor R3 adds hysteresis. It will typically be an order of magnitude greater than R1 or R2. The current through R1 and R2 should be at least 1μA to ensure that the 25nA (max) PFI input current does not shift the trip point. R3 should be larger than 10kΩ to prevent it from loading down the PFO pin. Capacitor C1 adds additional noise rejection.

### MONITORING A NEGATIVE VOLTAGE

The power-fail comparator can be used to monitor a negative supply voltage using the circuit shown in Figure 15. When the negative supply is valid, PFO is low. When the negative supply voltage drops, PFO goes high. This circuit's accuracy is affected by the PFI threshold tolerance, the VCC voltage, and resistors R1 and R2.

### BACKUP-BATTERY REPLACEMENT

The backup battery may be disconnected while VCC is above the reset threshold. No precautions are necessary to avoid spurious reset pulses.

Figure 15. Monitoring a Negative Voltage

### NEGATIVE-GOING V<sub>CC</sub> TRANSIENTS

The SP791 is relatively immune to short-duration negative-going V<sub>CC</sub> transients resulting from power up, power down, and brownout conditions. It is usually undesirable to reset the μP when V<sub>CC</sub> experiences only small glitches.

Typically, a V<sub>CC</sub> transient that goes 100mV below the reset threshold and lasts for 40μs or less will not cause a reset pulse to be issued.

A 100nF bypass capacitor mounted close to the V<sub>CC</sub> pin provides additional transient immunity.

### CONNECTING A TIMING CAPACITOR TO THE SWT PIN

To prevent timing errors minimize external current leakage sources at this pin, and locate the capacitor as close to SWT as possible. The sum of PC board leakage + SWT capacitor leakage must be small compared to ±100 nA.

### WATCHDOG SOFTWARE CONSIDERATIONS

A way to help the watchdog timer keep a closer watch on software execution involves setting and resetting the watchdog input at different points in the program, rather than "pulsing" the watchdog input high-low-high or low-high-low.

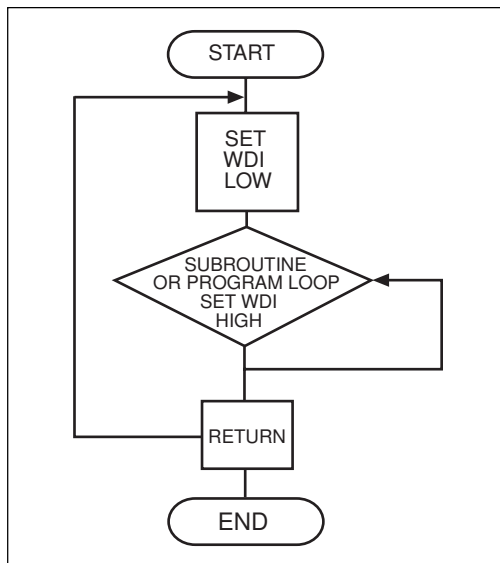

Figure 16. Watchdog Flow Diagram

This technique avoids a "stuck" loop where the watchdog timer continues to be reset within the loop, keeping the watchdog from timing out.

Figure 16 shows an example flow diagram where the I/O driving the watchdog input is set low at the beginning of the program, set high at the beginning of every subroutine or loop, then set low again when the program returns to the beginning. If the program should "hang" in any subroutine, the I/O is continually set high and the watchdog timer is allowed to time out, causing a reset or interrupt to be issued.

### MAXIMUM V<sub>CC</sub> FALL TIME

The V<sub>CC</sub> fall time is limited by the propagation delay of the battery switchover comparator and should not exceed 0.03V/μs. A standard rule of thumb for filter capacitance on most regulators is on the order of 100μF per amp of current. When the power supply is shut off or the main battery is disconnected, the associated initial V<sub>CC</sub> fall rate is just the inverse of 1A/100μF = 0.01V/μs. The V<sub>CC</sub> fall rate decreases with time as V<sub>CC</sub> falls exponentially, which more than satisfies the maximum fall-time requirement.
