

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

Adaptive 3.4 Gbps 3:1 TMDS/HDMI signal equalizer

Features

- Compatible with the high-definition multimedia interface (HDMI) v1.3 digital interface
- Conforms to the transition minimized differential signaling (TMDS) voltage standard on input and output channels
- 340 MHz maximum clock speed operation supports all video formats with deep color at maximum refresh rates
- 3.4 Gbps data rate per channel
- Fully automatic adaptive equalizer
- Single supply V_{CC} : 3.135 to 3.465 V
- ESD: $> \pm 5$ KV HBM for all TMDS I/Os
- Integrated open-drain I²C buffer for display data channel (DDC)
- 5.3 V tolerant DDC and HPD I/Os
- Lock-up free operation of I²C bus
- 0 to 400 kHz clock frequency for I²C bus
- Low capacitance of all the channels
- Equalizer regenerates the incoming attenuated TMDS signal
- Buffer drives the TMDS outputs over long PCB track lengths
- Low output skew and jitter
- Tight input thresholds reduce bit error rates
- On-chip selectable 50 Ω input termination
- Low ground bounce
- Data and control inputs provide undershoot clamp diode
- -40°C to 85°C operating temperature range
- Evaluation kit is available

Description

The STDVE003A integrates a 4-channel 3.4 Gbps TMDS equalizer and a 3:1 switch to select one of the three HDMI ports. The 3-input HDMI ports can be either external ports or internal sources. High-speed data paths and flow-through pinout minimize the internal device jitter and simplify the board layout. The equalizer overcomes the intersymbol interference (ISI) jitter effects from lossy cables. The buffer/driver on the output can drive the TMDS output signals over long distances. In addition to this, STDVE003A integrates the 50 Ω termination resistor on all the input channels to improve performance and reduce board space. The device can be placed in a low-power mode by disabling the output current drivers. The STDVE003A is ideal for advanced TV and STB applications supporting HDMI/DVI standard. The differential signal from the HDMI/DVI ports can be routed through the STDVE003A to guarantee good signal quality at the HDMI receiver. Designed for very low skew, jitter and low I/O capacitance, the switch preserves the signal integrity to pass the stringent HDMI compliance requirements.

3 Functional description

The STDVE003A routes physical layer signals for high bandwidth digital video and is compatible with low voltage differential signaling standard like TMDS. The device passes the differential inputs from a video source to a common display when it is in the active mode of operation. The device conforms to the TMDS standard on both inputs and outputs.

The low on-resistance and low I/O capacitance of the switch in STDVE003A result in a very small propagation delay. The device integrates SPDT-type switches for 3 differential data TMDS channels and 1 differential clock channel. Additionally, it integrates the switches for DDC and HPD line switching with I²C repeater on the DDC lines.

The I²C interface of the selected input port is linked to the I²C interface of the output port, and the hot plug detector (HPD) of the selected input port is output to HPD_SINK. For the unused ports, the I²C interfaces are isolated and the HPD pins are driven to L state.

3.1 Adaptive equalizer

The equalizer dramatically reduces the intersymbol interference (ISI) jitter and attenuation from long or lossy transmission media. The inputs present high impedance when the device is not active or when V_{CC} is absent or 0 V. In all other cases, the 50 Ω termination resistors on input channels are present.

This circuit helps to improve the signal eye pattern significantly. Shaping is performed by the gain stage of the equalizer to compensate the signal degradation and then the signals are driven on to the output ports.

The equalizer is fully adaptive and automatic in function providing smaller gain at low frequencies and higher gain at high frequencies. The default setting of EQ_BOOST = L is recommended for optimized operation.

Table 3. Gain frequency response

Frequency (MHz)	Gain in dB (EQ_BOOST = 0)	Gain in dB (EQ_BOOST = 1)
225	3	6.5
325	5	8.5
410	6.5	11
825	11	16
1650	16	21.5

Figure 6. STDVE003A gain vs. frequency

The STDVE003A equalizer is fully adaptive and automatic in function. The default setting of EQ_BOOST = L is recommended for optimal operation. The equalizer's performance is optimized for all frequencies over the cable lengths from 1 m to 25 m at EQ_BOOST = L. If cable lengths greater than 25 m are desired in application, then EQ_BOOST = H setting is recommended.

Input termination

The STDVE003A integrates precise $50 \Omega \pm 5\%$ termination resistors, pulled up to V_{CC} , on all its differential input channels. External terminations are not required. This gives better performance and also minimizes the PCB board space. These on-chip termination resistors should match the differential characteristic impedance of the transmission line. Since the output driver consists of current steering devices, an output voltage is not generated without a termination resistor. Output voltage levels are dependent on the value of the total termination resistance. The STDVE003A produces TMDs output levels for point-to-point links that are doubly terminated (100Ω at each end). With the typical 10 mA output current, the STDVE003A produces an output voltage of $3.3 - 0.5 V = 2.8 V$ when driving a termination line terminated at each end. The input terminations are selectable thus saving power for the unselected ports.

Output buffers

Each differential output of the STDVE003A drives external 50Ω load (pull-up resistor) and conforms to the TMDs voltage standard. The output drivers consist of 10 mA differential current-steering devices.

The driver outputs are short-circuit current limited and are high-impedance to ground when OE_N = H or the device is not powered. The current steering architecture requires a resistive load to terminate the signal to complete the transmission loop from V_{CC} to GND through the termination resistor. Because the device switches the direction of the current flow and not voltage levels, the output voltage swing is determined by V_{CC} minus the voltage drop across the termination resistor. The output current drivers are controlled by the OE_N pin and are turned off when OE_N is a high. A stable 10 mA current is derived by accurate internal current mirrors of a stable reference current which is generated by band-gap voltage

across the REXT. The differential output driver provides a typical 10 mA current sink capability, which provides a typical 500 mV voltage drop across a 50 Ω termination resistor.

TMDS voltage levels

The TMDS interface standard is a signaling method intended for point-to-point communication over a tightly controlled impedance medium. The TMDS standard uses a lower voltage swing than other common communication standards, achieving higher data rates with reduced power consumption while reducing EMI emissions and system susceptibility to noise. The device is capable of detecting differential signals as low as 100 mV within the entire common mode voltage range.

3.2 Operating modes

Table 4. OE_N operating modes

Input			Output		Function
OE_N	IN+ (ports A1, A2 or A3)	IN- (ports B1, B2 or B3)	OUT+	OUT-	
L	H	L	H	L	Active mode
L	L	H	L	H	Active mode
H	X	X	Hi-Z	Hi-Z	Low power mode

The OE_N input activates a hardware power down mode. When the power down mode is active (OE_N = H), all input and output buffers and internal bias circuitry are powered-off and disabled.

Outputs are tri-stated in power-down mode. When exiting power-down mode, there is a delay associated with turning on band-references and input/output buffer circuits.

3.2.1 SEL operating modes

The active source is selected by configuring source select inputs, S1, S2 and S3. The selected TMDS inputs from each port are switched through a 3-to-1 multiplexer. The I²C interface of the selected input port is linked to the I²C interface of the output port, and the hot plug detector (HPD) of the selected input port is output to HPD_SINK. For the unused ports, the I²C interfaces are isolated, and the HPD pins are kept low.

Table 5. SEL operating modes

Control pins			I/O selected		Hot-plug detect status		
S1	S2	S3	Y/Z	SCL_SINK SDA_SINK	HPD1	HPD2	HPD3
H	X	X	A1/B1	SCL1 SDA1	HPD_SINK	L	L
L	H	X	A2/B2	SCL2 SDA2	L	HPD_SINK	L
L	L	H	A3/B3	SCL3 SDA3	L	L	HPD_SINK
L	L	L	None (Z)	None (Z)	L	L	L

H: logic high; L: logic low; X: don't care; Z: high impedance

3.3 HPD pins

The input pin HPD_SINK is 5 V tolerant, allowing direct connection to 5 V signals. The switch is able to pass both 0 V and 5 V signal levels. The HPD_SINK is an input pin while the A_HPDP, B_HPDP and C_HPDP are open-drain outputs.

3.4 DDC channels

The DDC channels are designed with a bidirectional NMOS gate, providing 5 V signal tolerance. The 5 V tolerance allows direct connection to a standard I²C bus, thus eliminating the need for a level shifter. There should be external pull-up resistors on either side of the device on both the SCL and SDA lines.

3.5 I²C DDC line repeater

The device contains two identical bidirectional open-drain, non-inverting buffer circuits that enable I²C DDC bus lines to be extended without degradation in system performance. The STDVE003A buffers both the serial data (DDC SDA) and serial clock (DDC SCL) on the I²C bus, while retaining all the operating modes and features of the I²C system. This enables two buses of 400 pF bus capacitance to be connected in an I²C application. These buffers are operational from a supply V of 3.0 V to 3.6 V.

The I²C bus capacitance limit of 400 pF restricts the number of devices and bus length. The STDVE003A enables the system designer to isolate the two halves of a bus, accommodating more I²C devices or longer trace lengths. It can also be used to run two buses, one at 5 V and the other at 3.3 V or a 400 kHz and 100 kHz bus, where the 100 kHz bus is isolated when 400 kHz operation of the other bus is required. The STDVE003A can be used to run the I²C bus at both 5 V and 3.3 V interface levels.

The S1, S2 and S3 (SEL) lines act as control signals for the corresponding A, B or C ports. Note that the SEL line has an internal pull-down resistor. The SEL line should not change state during an I²C operation, because disabling during bus operation hangs the bus and enabling part way through a bus cycle could confuse the I²C parts being enabled. The SEL input should change state only when the global bus and the repeater port are in idle state, to prevent system failures.

The output low levels for each internal buffer are approximately 0.5 V, but the input voltage of each internal buffer must be 70 mV or more below the output low level, when the output internally is driven low. This prevents a lock-up condition from occurring when the input low condition is released.

As with the standard I²C system, pull up resistors are required to provide the logic high levels on the buffered bus. The STDVE003A has standard open collector configuration of the I²C bus. The size of the pull up resistors depends on the system, but each side of the repeater must have a pull up resistor.

This part is designed to work with standard mode and fast mode I²C devices. Standard mode I²C devices only specify 3 mA output drive, this limits the termination current to 3 mA in a generic I²C system where standard mode devices and multiple masters are possible. Under certain conditions, higher termination currents can be used.

3.6 Power-down condition

The OE_N is used to disable most of the internal circuitry of STDVE003A that puts the device in a low power mode of operation.

3.7 Bias

The bandgap reference voltage over the external R_{EXT} reference resistor sets the internal bias reference current. This current and its factors (achieved by employing highly accurate and well matched current mirror circuit topologies) are generated on-chip and used by several internal modules. The 10 mA current used by the transmitter block is also generated using this reference current. It is important to ensure that the R_{EXT} value is within the ±1% tolerance range of its typical value.

Table 6. Bias parameter

Parameter	Min	Typ	Max	Unit
Bandgap voltage	-	1.2	-	V

The output voltage swing depends on 3 components: supply voltage (V_{supply}), termination resistor (R_T) and current drive (I_{drive}). The supply voltage can vary from $3.3\text{ V} \pm 5\%$, termination resistor can vary from $50\ \Omega \pm 10\%$.

The voltage on the output is given by:

$$V_{\text{supply}} - I_{\text{drive}} \times R_T$$

The variation on I_{drive} must be controlled to ensure that the voltage on HDMI output is within the HDMI specification under all conditions.

This is achieved when:

$$400\text{ mV} \leq I_{\text{drive}} \times R_T \leq 600\text{ mV} \text{ with typical value centered at } 500\text{ mV}.$$

3.8 Timing between HPD and DDC

It is important to ensure that the I²C DDC interface is ready by the time the HPD detection is complete.

As soon as the discovery is finished by the HPD detection, the configuration data is exchanged between a source and sink through the I²C DDC interface. The STDVE003 Afs DDC interface is ready for communication as soon as the power supply to the chip is present and stable. When the desired port is enabled and the chip is out of shutdown mode, the I²C DDC lines can be used for communication.

Thus, as soon as the HPD detection sequence is complete, the DDC interface can be readily used. There is no delay between the HPD detection and I²C DDC interface to be ready.

4 Maximum rating

Stressing the device above the rating listed in the “absolute maximum ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 7. Absolute maximum ratings

Symbol	Parameter	Value	Unit

Table 12. DC specifications for OE_N, EQ_BOOST, SEL (S1, S2, S3) inputs

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V _{IH}	HIGH level input voltage	High level guaranteed	2.0			V
V _{IL}	LOW level input voltage	Low level guaranteed	-0.5		0.8	V
V _{IK}	Clamp diode voltage	V _{CC} = 3.465 V I _{IN} = -18 mA	-1.2	-0.8		V
I _{IH}	Input high current	V _{CC} = 3.465 V V _{IN} = V _{CC}	-5		+5	μA
I _{IL}	Input low current	V _{CC} = 3.465 V V _{IN} = GND	-5		+5	μA
C _{IN}	Input capacitance	Pin to GND F = 1 MHz		3.5		pF

Table 13. Input termination resistor

Symbol	Parameter	Test condition	Value			Unit
R _{TERM}	Differential input termination resistor on IN± channels relative to V _{CC}	I _{IN} = -10 mA	45	50	55	Ω

Table 14. External reference resistor

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
R _{EXT}	Resistor for TMDS compliant voltage swing range	Tolerance for R = ±1%		4.7		KΩ

Table 15. DDC I/O pins (switch)

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V _{I(DDC)}	Input voltage		GND		5.3	V

Table 15. DDC I/O pins (switch)

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
$I_{I(leak)}$	Input leakage current	$V_{CC} = 3.465\text{ V}$ A, B, C ports = 5.3 V Y port = 0.0 V Switch is isolated			6	μA
		$V_{CC} = 3.465\text{ V}$ A, B, C ports = 3.3 V Y port = 0.0 V Switch is isolated			2	μA
$C_{I/O}$	Input/output capacitance	$V_I = 0\text{ V}$ F = 1 MHz Switch disabled		5		pF
		$V_I = 0\text{ V}$ F = 1 MHz Switch enabled		9		pF

Table 16. Status pins (Y_HPDP)

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V_{IH}	High level input voltage	$V_{CC} = 3.3\text{ V}$ High level guaranteed	2.0		5.3	V
V_{IL}	Low level input voltage	$V_{CC} = 3.3\text{ V}$ Low level guaranteed	GND		0.8	V
$I_{I(leak)}$	Input leakage current	$V_{CC} = 3.465\text{ V}$ $Y = 5.3\text{ V}$			4	μA
		$V_{CC} = 3.465\text{ V}$ $Y = 3.3\text{ V}$			2	μA

Table 17. Status pins (A_HPDP, B_HPDP, C_HPDP)⁽¹⁾

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V	Voltage		GND		5.3	V
$C_{I/O}$	Input/output capacitance	$V_I = 0\text{ V}$ $F = 1\text{ MHz}$ Switch disabled		5		pF
		$V_I = 0\text{ V}$ $F = 1\text{ MHz}$ Switch enabled		9		pF
V_{OL}	Output low voltage (open drain I/Os)	$V_{CC} = 3.3\text{ V}$ $I_{OL} = 8\text{ mA}$			0.4	V

1. Typical parameters are measured at $V_{CC} = 3.3\text{ V}$, $T_A = +25\text{ }^\circ\text{C}$.

4.3 DC electrical characteristics (I²C repeater)

(T_A = -40 to +85 °C, V_{CC} = 3.3 V ± 5%, GND = 0 V; unless otherwise specified)

Table 18. Supplies

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V _{CC}	DC supply voltage		3.135	3.3	3.465	V

Table 19. Input/output SDA, SCL

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
V _{IH}	High level input voltage		0.7 V _{CC}		5.3	V
V _{IL}	Low level input voltage ⁽¹⁾		-0.5		0.3 V _{CC}	V
V _{ILc}	Low level input voltage contention ⁽¹⁾		-0.5		0.4	V
V _{IK}	Input clamp voltage	I _I = -18 mA	–	–	-1.2	V
I _{IL}	Input current low (SDA, SCL)	Input current low (SDA, SCL)	–	–	1	μA
I _{IH}	Input current high (SDA, SCL)	V _I = 3.465 V (SDA, SCL)	–	–	10	μA
		V _I = 5.3 V (SDA, SCL)	–	–	10	μA
V _{OL}	LOW-level output voltage	I _{OL} = 3 mA			0.4	V
		I _{OL} = 6 mA			0.65	V
I _{OH}	Output high level leakage current	V _O = 3.6 V; driver disabled	–	–	10	μA
		V _O = 5.3 V; driver disabled	–	–	10	μA
C _I	Input capacitance	V _I = 3 V or 0 V	–	6	7 ⁽²⁾	pF

1. V_{IL} specification is for the first low level seen by the SDA/SCL lines. V_{ILc} is for the second and subsequent low levels seen by the SDA/SCL lines.
2. The SCL/SDA C_I is about 200 pF when V_{CC} = 0 V. The STDVE003A should be used in applications where power is secured to the repeater but an active bus remains on either set of the SDA/SCL pins.

4.4 Dynamic switching characteristics^(b)

$T_A = -40$ to $+85$ °C, $V_{CC} = 3.3$ V \pm 5%, $R_{TERM} = 50$ Ω \pm 5%, $C_L = 5$ pF).

Typical values are at $T_A = +25$ °C and $V_{CC} = 3.3$ V.

Table 20. Clock and data rate

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
f_{CK}	Clock frequency (1/10th of the differential data rate)		25		340	MHz
D_{rate}	Signaling rate				3.4	Gbps

Table 21. Equalizer gain

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
G_{EQ}	Equalizer gain	At all frequencies (EQ_BOOST = L) for short cables		15		dB
		At all frequencies (EQ_BOOST = H) for long cables		20		dB

Table 22. Differential output timings

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
t_r	Differential data and clock output rise/fall times	20% to 80% of V_{OD}	75	150	240	ps
t_f		80% to 20% of V_{OD}	75	150	240	ps
t_{PLH}	Differential low to high propagation delay	Alternating 1 and 0 pattern at slow and fast data rates	250		800	ps
t_{PHL}	Differential high to low propagation delay	Measure at 50% V_{OD} between input to output	250		800	ps

b. *The timing values in this section are tested during characterization and are guaranteed by design and simulation. Not tested in production.*

Table 23. Skew times

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
$t_{SK(O)}$	Inter-pair channel-to-channel output skew				100	ps
$t_{SK(P)}$	Pulse skew	$ t_{PLH} - t_{PHL} $		25	80	ps
$t_{SK(D)}$	Intra-pair differential skew				44	ps
$t_{SK(CC)}$	Output channel to channel skew	Difference in propagation delay (t_{PLH} or t_{PHL}) among all output channels		50	125	ps

Table 24. Turn-on and turn-off times

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
t_{ON}	TMDS output enable time	Time from OE_N to OUT± change from tri-state to active		12	20	ns
t_{OFF}	TMDS output disable time	Time from OE_N to OUT± change from active to tri-state		6	10	ns

Table 25. DDC I/O pins

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
Refer to Section 4.5						

Table 26. Status pins (Y_HPD, A_HPD, B_HPD, C_HPD, SEL)

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
$t_{PD(HPD)}$	Propagation delay (from Y_HPD to the active port of HPD)	$C_L = 10 \text{ pF}$, $R_{PU} = 1 \text{ K}\Omega$		150		ns
$T_{ON/OFF}$	Switch time (from port select to the latest valid status of HPD)	$C_L = 10 \text{ pF}$		50		ns

Table 27. Jitter

Symbol	Parameter	Test condition	Value			Unit
			Min	Typ	Max	
t_{JIT}	Total jitter ⁽¹⁾	PRBS pattern at 1.6 Gbps (800 MHz)		35		ps (p-p)

1. Total jitter is measured peak-to-peak with a histogram including 3500 window hits. Stimulus and fixture jitter has been subtracted. Input differential voltage = $V_{ID} = 500$ mV, PRBS random pattern at 1.65 Gbps, $t_r=t_f=50$ ps (20% to 80%). Jitter parameter is not production-tested but guaranteed through characterization on a sample-to-sample basis.
