

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

100 W motor control power board based on STIPN2M50T-H SLLIMM™ nano IPM

Introduction

The STEVAL-IPMnM2N is a compact motor drive power board based on SLLIMM-nano™ (small low-loss intelligent molded module) IPM MOSFET-based (STIPN2M50T-H). It provides an affordable and easy-to-use solution for driving high power motors for a wide range of applications such as power white goods, air conditioning, compressors, power fans and 3-phase inverters for motor drives in general. The IPM itself consists of short-circuit rugged MOSFETs and a wide range of features like undervoltage lockout, smart shutdown, embedded temperature sensor and NTC, and overcurrent protection.

The main characteristics of this evaluation board are small size, minimal BOM and high efficiency. It consists of an interface circuit (BUS and V_{CC} connectors), bootstrap capacitors, snubber capacitor, hardware short-circuit protection, fault event and temperature monitoring. In order to increase the flexibility, it is designed to work in single- or three-shunt configuration and with triple current sensing options: three dedicated onboard op-amps, an internal IPM op-amp and op-amps embedded in the MCU. The Hall/Encoder section completes the circuit.

With these advanced characteristics, the system is designed to achieve fast and accurate current feedback conditioning, satisfying the typical requirements for field-oriented control (FOC).

The STEVAL-IPMnM2N is compatible with ST's STM32-based control board, enabling designers to build a complete platform for motor control.

Figure 1. Motor control board (top view) based on SLLIMM-nano™ MOSFET

1 Key features

- Input voltage: 125 - 400 V_{DC}
- Nominal power: up to 100 W
- Nominal current: up to 1.2 A_{rms}
- Input auxiliary voltage: up to 20 V_{DC}
- Motor control connector (32 pins) interfacing with ST MCU boards
- Single- or three-shunt resistors for current sensing (with sensing network)
- Three options for current sensing: external dedicated op-amps, internal SLLIMM-nano op-amp (single) or through MCU
- Overcurrent hardware protection
- IPM temperature monitoring and protection
- Hall sensors (3.3 / 5 V)/encoder inputs (3.3 / 5 V)
- MOSFET intelligent power module:
 - SLLIMM-nano™ IPM MOSFET-based (STIPN2M50T-H - Full molded package package)
- Universal design for further evaluation with bread board and testing pins
- Very compact size

Figure 2. Motor control board (bottom view) based on SLLIMM-nano™ MOSFET

2 Circuit schematics

The full schematics for the SLLIMM-nano™ MOSFET card for [STIPN1M50T-H](#) IPM products is shown below. This card consists of an interface circuit (BUS and V_{CC} connectors), bootstrap capacitors, snubber capacitor, short-circuit protection, fault output circuit, temperature monitoring, single-/three-shunt resistors and filters for input signals. It also includes bypass capacitors for V_{CC} and bootstrap capacitors. The capacitors are located very close to the drive IC to avoid malfunction due to noise.

Three current sensing options are provided: three dedicated onboard op-amps, one internal IPM op-amp and the embedded MCU op-amps; selection is performed through three jumpers.

The Hall/Encoder section (powered at 5 V or 3.3 V) completes the circuit.

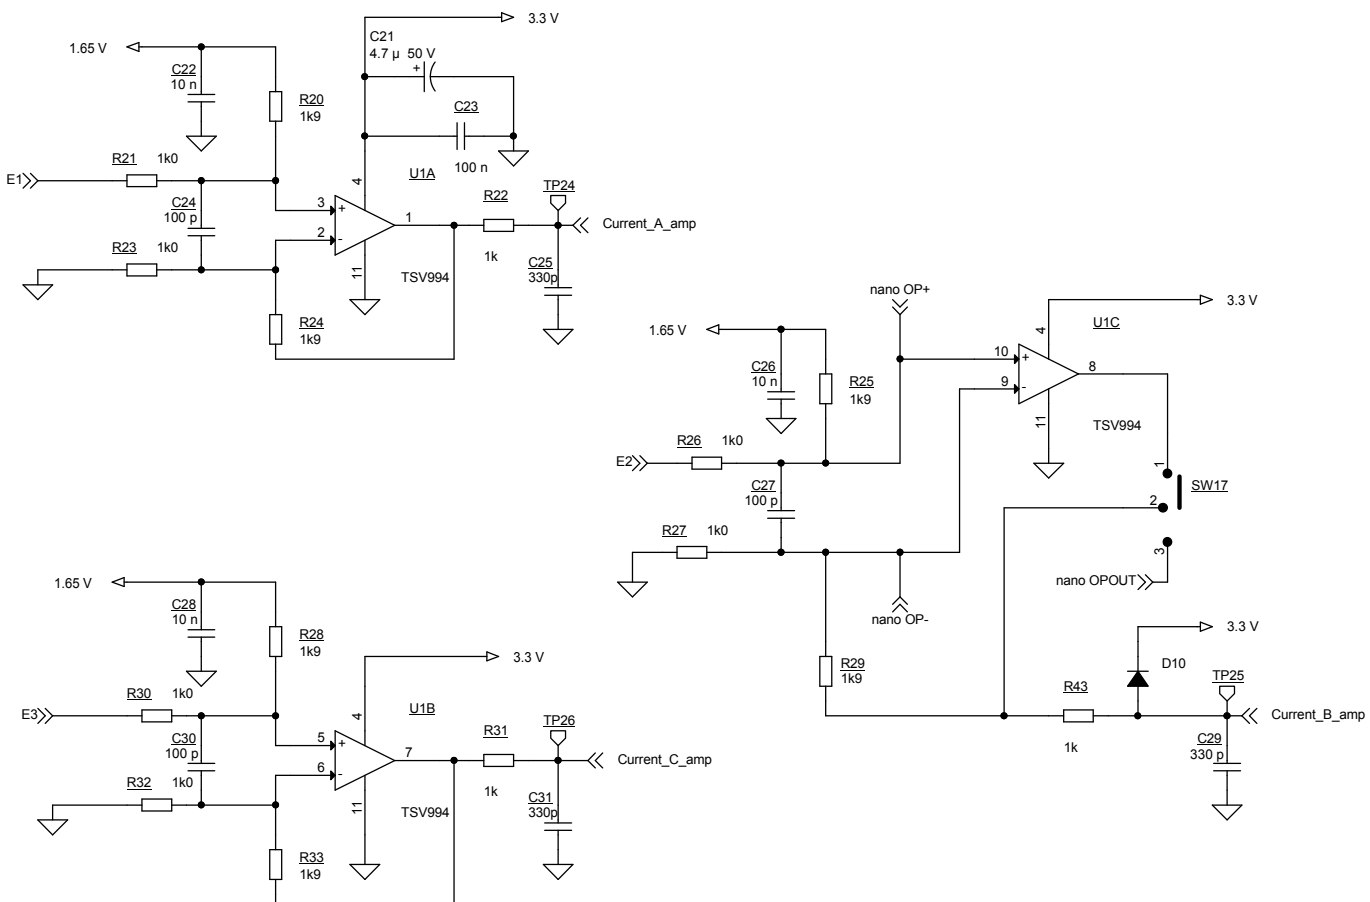

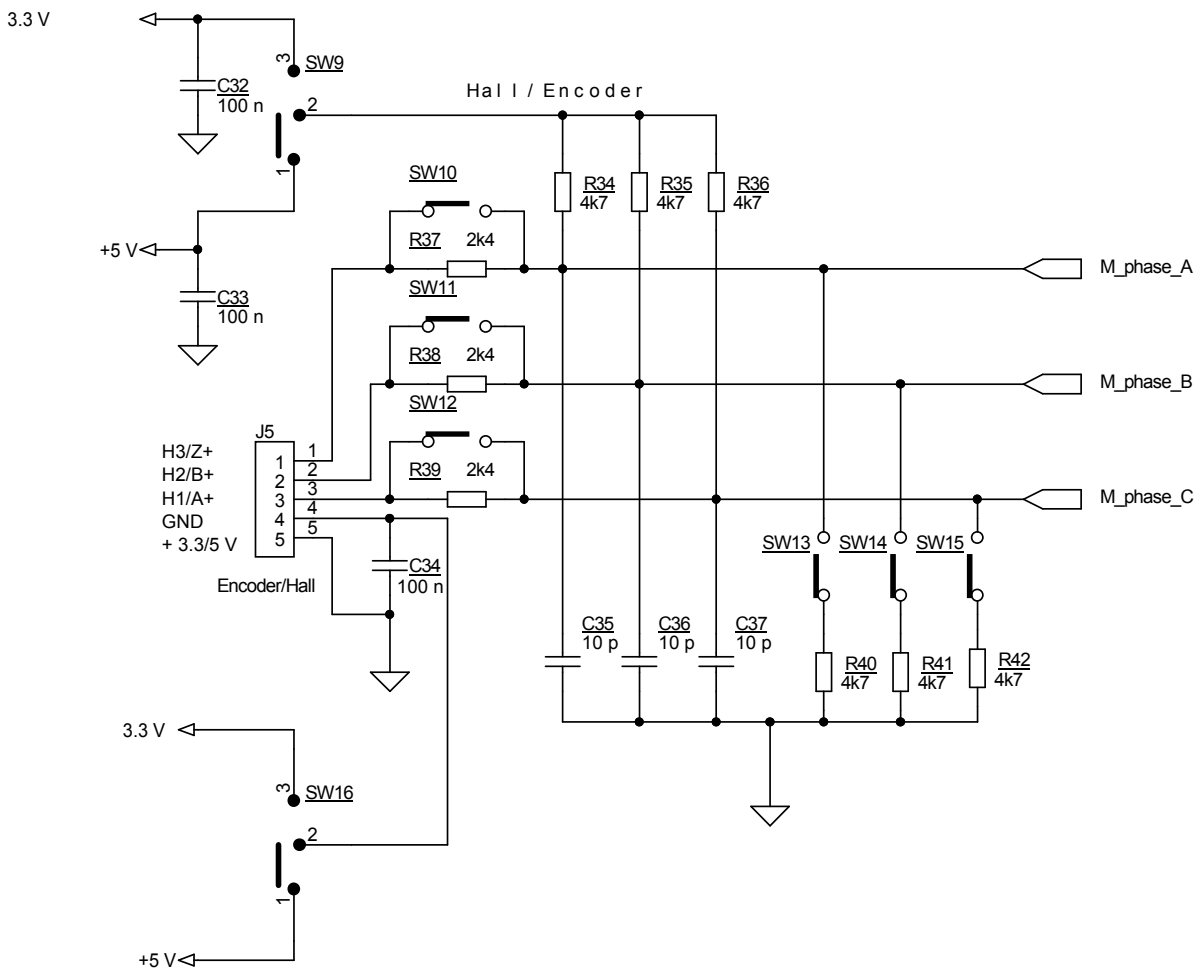

Figure 7. STEVAL-IPMmM2N circuit schematic (5 of 5)

3 Filters and key parameters

3.1 Input signals

The input signals (LINx and HINx) to drive the internal MOSFETs are active high. A 375 k Ω (typ.) pull-down resistor is built-in for each input signal. To prevent input signal oscillation, an RC filter is added on each input as close as possible to the IPM. The filter is designed using a time constant of 10 ns (1 k Ω and 10 pF).

3.2 Bootstrap capacitor

In the 3-phase inverter, the emitters of the low side MOSFETs are connected to the negative DC bus (V_{DC-}) as common reference ground, which allows all low side gate drivers to share the same power supply, while the emitter of the high side MOSFETs is alternately connected to the positive (V_{DC+}) and negative (V_{DC-}) DC bus during running conditions.

A bootstrap method is a simple and cheap solution to supply the high voltage section. This function is normally accomplished by a high voltage fast recovery diode. The SLLIMM-nano 2 MOSFET -based family includes a patented integrated structure that replaces the external diode with a high voltage DMOS functioning as a diode with series resistor. An internal charge pump provides the DMOS driving voltage.

The value of the C_{BOOT} capacitor should be calculated according to the application requirements.

Figure 8. C_{BOOT} graph selection shows the behavior of C_{BOOT} (calculated) versus switching frequency (f_{sw}), with different values of ΔV_{CBOOT} for a continuous sinusoidal modulation and a duty cycle $\delta = 50\%$.

Note: This curve is taken from application note AN4840 (available on www.st.com); calculations are based on the STGIP5C60T-Hyy device, which represents the worst case scenario for this kind of calculation.

The boot capacitor must be two or three times larger than the C_{BOOT} calculated in the graph.

For this design, a value of 2.2 μF was selected.

Figure 8. C_{BOOT} graph selection

3.3 Overcurrent protection

The SLLIMM-nano MOSFET -based integrates a comparator for fault sensing purposes. The comparator has an internal voltage reference V_{REF} (540 mV typ.) connected to the inverting input, while the non-inverting input on the CIN pin can be connected to an external shunt resistor to implement the overcurrent protection function. When the comparator triggers, the device enters the shutdown state.

The comparator output is connected to the \overline{SD} pin in order to send the fault message to the MCU.

3.3.1 SD pin

The \overline{SD} is an input/output pin (open drain type if used as output) used for enable and fault; it is shared with NTC thermistor, internally connected to GND.

The pull-up resistor (R10) causes the voltage V_{SD-GND} to decrease as the temperature increases. To maintain the voltage above the high-level logic threshold, the pull-up resistor is sized at 1 k Ω (3.3 V MCU power supply).

The filter on \overline{SD} (R10 and C18) must be sized to obtain the desired re-starting time after a fault event and placed as close as possible to the pin.

A shutdown event can be managed by the MCU; in which case, the SD functions as the input pin.

Conversely, the SD functions as an output pin when an overcurrent or undervoltage condition is detected.

3.3.2 Shunt resistor selection

The value of the shunt resistor is calculated by the following equation:

$$R_{SH} = \frac{V_{ref}}{I_{OC}} \quad (1)$$

Where V_{ref} is the internal comparator (CIN) (0.54 V typ.) and I_{OC} is the overcurrent threshold detection level.

The maximum OC protection level should be set to less than the pulsed collector current in the datasheet. In this design, the overcurrent threshold level is fixed at $I_{OC} = 2.6$ A in order to select a commercial shunt resistor value.

$$R_{SH} = \frac{V_{ref} \cdot \left(\frac{R15 + R11}{R11} \right) + V_F}{I_{OC}} = \frac{0.54 \cdot \left(\frac{1000 + 4700}{4700} \right) + 0.18}{2.6} = 0.321 \Omega \quad (2)$$

Where V_F is the voltage drop across diodes D3, D4 and D5.

For the power rating of the shunt resistor, the following parameters must be considered:

- Maximum load current of inverter (85% of I_{nom} [Arms]): $I_{load(max)}$
- Shunt resistor value at TC = 25 °C
- Power derating ratio of shunt resistor at $T_{SH} = 100$ °C
- Safety margin

The power rating is calculated by the following equation:

$$P_{SH} = \frac{1}{2} \cdot \frac{I_{load(max)}^2 \cdot R_{SH} \cdot margin}{Derating\ ratio} \quad (3)$$

The commercial value chosen was 0.66 Ω to which corresponds an overcurrent level of 2.5 A.

The power rating is:

$$\begin{aligned} I_{nom} = 2A \rightarrow I_{nom[rms]} &= \frac{I_{nom}}{\sqrt{2}} \rightarrow I_{load(max)} = 85\% \left(I_{nom[rms]} \right) \\ &= 1.2 A_{rms} \end{aligned} \quad (4)$$

- Power derating ratio of shunt resistor at TSH = 100 °C: 80% (from datasheetmanufacturer)
- Safety margin: 30%

$$P_{SH} = \frac{1}{2} \cdot \frac{1.2^2 \cdot 0.33 \cdot 1.3}{0.8} = 0.38 W \quad (5)$$

Considering the commercial value, a 1 W shunt resistor was selected.

Based on the previous equations and conditions, the minimum shunt resistance and power rating is summarized below.

Table 1. Shunt selection

Device	$I_{nom(peak)}$ [A]	$OCP_{(peak)}$ [A]	$I_{load(max)}$ [Arms]	R_{SHUNT} [Ω]	Minimum shunt power rating P_{SH} [W]
STIPN2M50T-H	2	2.5	1.2	0.33	0.38

3.3.3 CIN RC filter

An RC filter network on the CIN pin is required to prevent short-circuits due to the noise on the shunt resistor. In this design, the R15-C8 RC filter has a constant time of about 1 μs .

3.3.4 Single- or three-shunt selection

Single- or three-shunt resistor circuits can be adopted by setting the solder bridges SW5, SW6, SW7 and SW8. The figures below illustrate how to set up the two configurations.

Figure 9. One-shunt configuration

Figure 10. Three-shunt configuration

Further details regarding sensing configuration are provided in the next section.

4 Current sensing amplifying network

The STEVAL-IPMnM2N motor control evaluation board can be configured to run in three-shunt or single-shunt configurations for field oriented control (FOC).

The current can be sensed thanks to the shunt resistor and amplified by using the on-board operational amplifiers or by the MCU (if equipped with op-amp).

Once the shunt configuration is chosen by setting solder bridge on SW5, SW6, SW7 and SW8 (as described in the previous section), the user can choose whether to send the voltage shunt to the MCU amplified or not amplified.

Single-shunt configuration requires a single op amp so the only voltage sent to the MCU to control the sensing is connected to phase V through SW2.

Switch SW17 is used to send amplified signal coming from the internal IPM op-amp or from an external one.

SW1, SW2, SW3 and SW17 can be configured to select which signals are sent to the microcontroller, as per the following table.

Table 2. Op-amp sensing configuration

Configuration	Sensing	Bridge (SW1)	Bridge (SW2)	Bridge (SW3)	Bridge (SW17)
Single Shunt	IPM op-amp	open	1-2	open	2-3
	On board op-amp	open	1-2	open	1-2
	MCU op-amp	open	2-3	open	1-2
Three Shunt	On board op-amp	1-2	1-2	1-2	1-2
	MCU op-amp	2-3	2-3	2-3	1-2

The operational amplifier TSV994 used on the amplifying networks has a 20 MHz gain bandwidth from a single positive supply of 3.3 V.

The amplification network must allow bidirectional current sensing, so an output offset $V_O = +1.65$ V represents zero current.

For the STIPN2M50T-H ($I_{OCP} = 2.5$ A; $R_{SHUNT} = 0.33$ Ω), the maximum measurable phase current, considering that the output swings from +1.65 V to +3.3 V (MCU supply voltage) for positive currents and from +1.65 V to 0 for negative currents is:

Equation 5

$$MaxMeasCurrent = \frac{\Delta V}{r_m} = 2.5 \text{ A} \quad (6)$$

$$r_m = \frac{\Delta V}{MaxMeasCurrent} = \frac{1.65}{2.5} = 0.66 \text{ } \Omega \quad (7)$$

The overall trans-resistance of the two-port network is:

$$r_m = R_{SHUNT} \cdot AMP = 0.33 \cdot AMP = 0.66 \text{ } \Omega \quad (8)$$

$$AMP = \frac{r_m}{R_{SHUNT}} = \frac{0.66}{0.33} = 2 \quad (9)$$

Finally choosing $R_a=R_b$ and $R_c=R_d$, the differential gain of the circuit is:

$$AMP = \frac{R_c}{R_a} = 1.9 \quad (10)$$

An amplification gain of 1.9 was chosen. The same amplification is obtained for all the other devices, taking into account the OCP current and the shunt resistance, as described in Table 1.

The RC filter for output amplification is designed to have a time constant that matches noise parameters in the range of 1.5 μ s:

$$4 \cdot \tau = 4 \cdot R_e \cdot C_c = 1.5 \text{ } \mu\text{s} \quad (11)$$

$$C_c = \frac{1.5 \mu s}{4 \cdot 1000} = 375 pF \left(330 pF \text{ selected} \right) \quad (12)$$

Table 3. Amplifying networks

Phase	Amplifying network			Rd	RC filter	
	Ra	Rb	Rc		Re	Cc
Phase U	R21	R23	R20	R24	R22	C25
Phase V	R26	R27	R25	R29	R43	C29
Phase W	R30	R32	R28	R33	R31	C31

5 Temperature monitoring

The SLLIMM-nano MOSFET family integrates an NTC thermistor placed close to the power stage. The board is designed to use it in sharing with the $\overline{\text{SD}}$ pin. Monitoring can be enabled and disabled via the SW4 switch.

5.1 NTC Thermistor

The built-in thermistor (85 k Ω at 25 °C) is inside the IPM and connected on $\overline{\text{SD}}$ /OD pin2 (shared with the SD function).

Given the NTC characteristic and the sharing with the $\overline{\text{SD}}$ function, the network is designed to keep the voltage on this pin higher than the minimum voltage required for the pull up voltage on this pin over the whole temperature range.

Considering $V_{\text{bias}} = 3.3 \text{ V}$, a pull up resistor of 1 k Ω (R10) was used.

The figure below shows the typical voltage on this pin as a function of device temperature.

Figure 11. NTC voltage vs temperature

6 Firmware configuration for STM32 PMSM FOC SDK

The following table summarizes the parameters which customize the latest version of the ST FW motor control library for permanent magnet synchronous motors (PMSM): STM32 PMSM FOC SDK for this STEVAL-IPMnM2N.

Table 4. ST motor control workbench GUI parameters - STEVAL-IPMnM2N

Block	Parameter	Value
Over current protection	Comparator threshold	$V_{ref} \cdot \left(\frac{R15 + R11}{R11} \right) + V_F = 0.83 \text{ V}$ (13)
	Overcurrent network offset	0
	Overcurrent network gain	0.1 V/A
Bus voltage sensing	Bus voltage divider	1/125
Rated bus voltage info	Min rated voltage	125 V
	Max rated voltage	400 V
	Nominal voltage	325 V
Current sensing	Current reading typology	Single- or three-shunt
	Shunt resistor value	0.33 Ω
	Amplifying network gain	1.9
Command stage	Phase U Driver	HS and LS: Active high
	Phase V Driver	HS and LS: Active high
	Phase W Driver	HS and LS: Active high

9 PCB design guide

Optimization of PCB layout for high voltage, high current and high switching frequency applications is a critical point. PCB layout is a complex matter as it includes several aspects, such as length and width of track and circuit areas, but also the proper routing of the traces and the optimized reciprocal arrangement of the various system elements in the PCB area.

A good layout can help the application to properly function and achieve expected performance. On the other hand, a PCB without a careful layout can generate EMI issues, provide overvoltage spikes due to parasitic inductance along the PCB traces and produce higher power loss and even malfunction in the control and sensing stages.

In general, these conditions were applied during the design of the board:

- PCB traces designed as short as possible and the area of the circuit (power or signal) minimized to avoid the sensitivity of such structures to surrounding noise.
- Good distance between switching lines with high voltage transitions and the signal line sensitive to electrical noise.
- The shunt resistors were placed as close as possible to the low side pins of the SLLIMM. To decrease the parasitic inductance, a low inductance type resistor (SMD) was used.
- RC filters were placed as close as possible to the SLLIMM pins in order to increase their efficiency.

9.1 Layout of reference board

All the components are inserted on the top of the board. Only the IPM module is inserted on the bottom to allow the insertion of a suitable heatsink for the application.

Figure 12. Silk screen and etch - top side

Figure 13. Silk screen and etch - bottom side

10 Recommendations and suggestions

- The BOM list is not provided with a bulk capacitor already inserted in the PCB. However, the necessary space has been included (C1). In order to obtain a stable bus supply voltage, it is advisable to use an adequate bulk capacity. For general motor control applications, an electrolytic capacitor of at least 100 μF is suggested.
- Similarly, the PCB does not come with a heat sink. You can place one above the IPM on the back side of the PCB with thermal conductive foil and screws. R_{TH} is an important factor for good thermal performance and depends on certain factors such as current phase, switching frequency, power factor and ambient temperature.
- The board requires +5 V and +3.3 V to be supplied externally through the 34-pin motor control connector J2. Please refer to the relevant board manuals for information on key connections and supplies.

11 General safety instructions

Danger:

The evaluation board works with high voltage which could be deadly for the users. Furthermore all circuits on the board are not isolated from the line input. Due to the high power density, the components on the board as well as the heat sink can be heated to a very high temperature, which can cause a burning risk when touched directly. This board is intended for use by experienced power electronics professionals who understand the precautions that must be taken to ensure that no danger or risk may occur while operating this board.

Caution:

After the operation of the evaluation board, the bulk capacitor C1 (if used) may still store a high energy for several minutes. So it must be first discharged before any direct touching of the board.

Important:

To protect the bulk capacitor C1, we strongly recommended using an external brake chopper after C1 (to discharge the high brake current back from the induction motor).
