

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

TOSHIBA MOS DIGITAL INTEGRATED CIRCUIT SILICON GATE CMOS

**1G BIT (128M × 8 BIT) CMOS NAND E<sup>2</sup>PROM****DESCRIPTION**

The TC58NVG0S3HBAI6 is a single 3.3V 1Gbit (1,140,850,688bits) NAND Electrically Erasable and Programmable Read-Only Memory (NAND E<sup>2</sup>PROM) organized as (2048 + 128) bytes × 64 pages × 1024 blocks. The device has a 2176-byte static registers which allow program and read data to be transferred between the register and the memory cell array in 2176-byte increments. The Erase operation is implemented in a single block unit (128 Kbytes + 8 Kbytes: 2176 bytes × 64 pages).

The TC58NVG0S3HBAI6 is a serial-type memory device which utilizes the I/O pins for both address and data input/output as well as for command inputs. The Erase and Program operations are automatically executed making the device most suitable for applications such as solid-state file storage, voice recording, image file memory for still cameras and other systems which require high-density non-volatile memory data storage.

**FEATURES**

- Organization
  - Memory cell array           x8  
                                  2176 × 64K × 8
  - Register                    2176 × 8
  - Page size                   2176 bytes
  - Block size                  (128K + 8K) bytes
- Modes
  - Read, Reset, Auto Page Program, Auto Block Erase, Status Read, Page Copy
- Mode control
  - Serial input/output
  - Command control
- Number of valid blocks
  - Min 1004 blocks
  - Max 1024 blocks
- Power supply
  - VCC = 2.7V to 3.6V
- Access time
  - Cell array to register    25 μs max
  - Serial Read Cycle        25 ns min (CL=50pF)
- Program/Erase time
  - Auto Page Program       300 μs/page typ.
  - Auto Block Erase        2.5 ms/block typ.
- Operating current
  - Read (25 ns cycle)       30 mA max.
  - Program (avg.)           30 mA max
  - Erase (avg.)             30 mA max
  - Standby                  50 μA max
- Package
  - P-VFBGA67-0608-0.80-001 (Weight: 0.095 g typ.)
- 8 bit ECC for each 512Byte is required.

Output load	$C_L$ (50 pF) + 1 TTL

Note: Busy to ready time depends on the pull-up resistor tied to the  $\overline{RY}/\overline{BY}$  pin.  
(Refer to Application Note (9) toward the end of this document.)

## PROGRAMMING AND ERASING CHARACTERISTICS

( $T_a = -40$  to  $85^\circ\text{C}$ ,  $V_{CC} = 2.7$  to  $3.6\text{V}$ )

SYMBOL	PARAMETER	MIN	TYP.	MAX	UNIT	NOTES
$t_{\text{PROG}}$	Average Programming Time	—	300	700	$\mu\text{s}$	
$t_{\text{DCBSYW2}}$	Data Cache Busy Time in Write Cache (following 15h)	—	—	700	$\mu\text{s}$	(2)
N	Number of Partial Program Cycles in the Same Page	—	—	4		(1)
$t_{\text{BERASE}}$	Block Erasing Time	—	2.5	5	ms	

(1) Refer to Application Note (12) toward the end of this document.

(2)  $t_{\text{DCBSYW2}}$  depends on the timing between internal programming time and data in time.

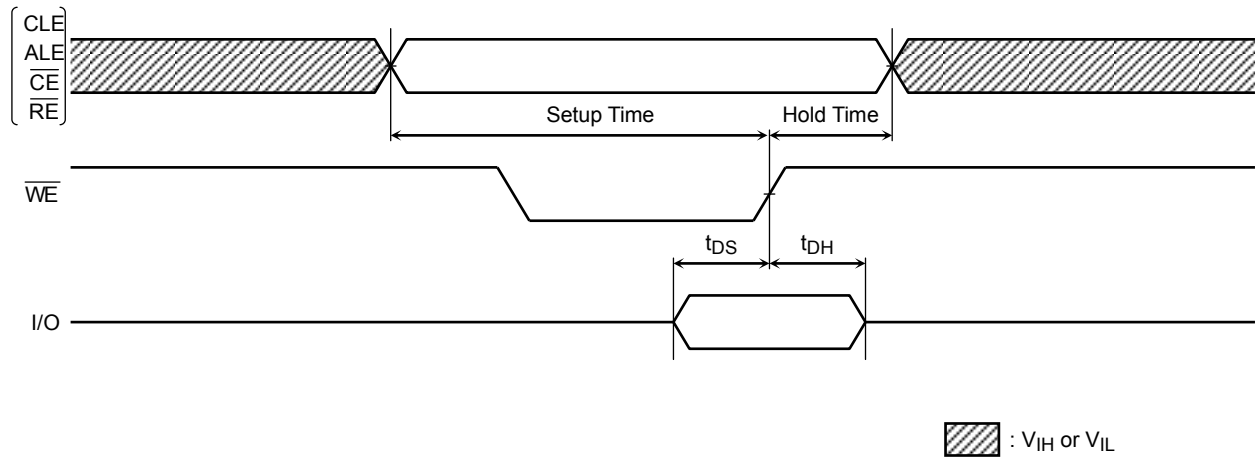

## Data Output

When  $t_{\text{REH}}$  is long, output buffers are disabled by  $\overline{RE}=\text{High}$ , and the hold time of data output depend on  $t_{\text{RHOH}}$  (25ns MIN). On this condition, waveforms look like normal serial read mode.

When  $t_{\text{REH}}$  is short, output buffers are not disabled by  $\overline{RE}=\text{High}$ , and the hold time of data output depend on  $t_{\text{RLOH}}$  (5ns MIN). On this condition, output buffers are disabled by the rising edge of  $\overline{CLE}$ ,  $\overline{ALE}$ ,  $\overline{CE}$  or falling edge of  $\overline{WE}$ , and waveforms look like Extended Data Output Mode.

(\*1)  $t_{PROG}$ : Since the last page programming by 10h command is initiated after the previous cache program, the  $t_{PROG}$  during cache programming is given by the following equation.

$$t_{PROG} = t_{PROG} \text{ of the last page} + t_{PROG} \text{ of the previous page} - A$$

$$A = (\text{command input cycle} + \text{address input cycle} + \text{data input cycle time of the last page})$$

If "A" exceeds the  $t_{PROG}$  of previous page,  $t_{PROG}$  of the last page is  $t_{PROG} \text{ max}$ .

(Note) Make sure to terminate the operation with 80h-10h- command sequence.  
 If the operation is terminated by 80h-15h command sequence, monitor I/O 6 (Ready / Busy) by issuing Status Read command (70h) and make sure the previous page program operation is completed. If the page program operation is completed issue FFh reset before next operation.

## PIN FUNCTIONS

The device is a serial access memory which utilizes time-sharing input of address information.

### Command Latch Enable: CLE

The CLE input signal is used to control loading of the operation mode command into the internal command register. The command is latched into the command register from the I/O port on the rising edge of the  $\overline{WE}$  signal while CLE is High.

### Address Latch Enable: ALE

The ALE signal is used to control loading address information into the internal address register. Address information is latched into the address register from the I/O port on the rising edge of  $\overline{WE}$  while ALE is High.

### Chip Enable: $\overline{CE}$

The device goes into a low-power Standby mode when  $\overline{CE}$  goes High during the device is in Ready state. The  $\overline{CE}$  signal is ignored when device is in Busy state ( $RY/\overline{BY} = L$ ), such as during a Program or Erase or Read operation, and will not enter Standby mode even if the  $\overline{CE}$  input goes High.

### Write Enable: $\overline{WE}$

The  $\overline{WE}$  signal is used to control the acquisition of data from the I/O port.

### Read Enable: $\overline{RE}$

The  $\overline{RE}$  signal controls serial data output. Data is available  $t_{REA}$  after the falling edge of  $\overline{RE}$ . The internal column address counter is also incremented (Address = Address + 1) on this falling edge.

### I/O Port: I/O1 to 8

The I/O1 to 8 pins are used as a port for transferring address, command and input/output data to and from the device.

### Write Protect: $\overline{WP}$

The  $\overline{WP}$  signal is used to protect the device from accidental programming or erasing. The internal voltage regulator is reset when  $\overline{WP}$  is Low. This signal is usually used for protecting the data during the power-on/off sequence when input signals are invalid.

### Ready/Busy: $RY/\overline{BY}$

The  $RY/\overline{BY}$  output signal is used to indicate the operating condition of the device. The  $RY/\overline{BY}$  signal is in Busy state ( $RY/\overline{BY} = L$ ) during the Program, Erase and Read operations and will return to Ready state ( $RY/\overline{BY} = H$ ) after completion of the operation. The output buffer for this signal is an open drain and has to be pulled-up to  $V_{ccq}$  with an appropriate resistor.

If  $RY/\overline{BY}$  signal is not pulled-up to  $V_{ccq}$  ("Open" state), device operation can not guarantee.

Schematic Cell Layout and Address Assignment

The Program operation works on page units while the Erase operation works on block units.

A page consists of 2176 bytes in which 2048 bytes are used for main memory storage and 128 bytes are for redundancy or for other uses.

1 page = 2176 bytes

1 block = 2176 bytes × 64 pages = (128K + 8K) bytes

Capacity = 2176 bytes × 64pages × 1024 blocks

An address is read in via the I/O port over four consecutive clock cycles, as shown in Table 1.

Table 1. Addressing

## Operation Mode: Logic and Command Tables

The operation modes such as Program, Erase, Read and Reset are controlled by command operations shown in Table 3. Address input, command input and data input/output are controlled by the CLE, ALE,  $\overline{CE}$ ,  $\overline{WE}$ ,  $\overline{RE}$  and  $\overline{WP}$  signals, as shown in Table 2.
