

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts,Customers Priority,Honest Operation,and Considerate Service",our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

FlexRay node transceiver

Rev. 1 — 10 October 2012

Product data sheet

## 1. General description

The TJA1083 FlexRay node transceiver is compliant with the FlexRay Electrical Physical Layer specification V3.0.1 (see [Ref. 1](#)). In order to meet JASPAR the requirements, it implements the 'Increased voltage amplitude transmitter' functional class. It is primarily intended for communication systems operating at between 2.5 Mbit/s and 10 Mbit/s, and provides an advanced interface between the protocol controller and the physical bus in a FlexRay network. The TJA1083 offers an optimized solution for Electronic Control Unit (ECU) applications that do not need enhanced power management and are typically switched by the ignition or activated by a dedicated wake-up line.

The TJA1083 provides a differential transmit capability to the network and a differential receive capability to the FlexRay controller. It offers excellent ElectroMagnetic Compatibility (EMC) performance as well as high ElectroStatic Discharge (ESD) protection.

The TJA1083 actively monitors system performance using dedicated error and status information (readable by any microcontroller), as well as internal voltage and temperature monitoring.

## 2. Features and benefits

### 2.1 Optimized for time triggered communication systems

- Compliant with Electrical Physical Layer specification V3.0.1
- Meets JASPAR requirements as described in the 'Bus driver increased voltage amplitude transmitter' functional class
- Automotive product qualification in accordance with AEC-Q100
- Data transfer rates from 2.5 Mbit/s to 10 Mbit/s
- Supports 60 ns minimum bit time at 400 mV differential input voltage
- Very low ElectroMagnetic Emission (EME) to support unshielded cable
- Differential receiver with high common-mode range for excellent ElectroMagnetic Immunity (EMI)
- Auto I/O level adaptation to host controller supply voltage  $V_{IO}$
- Can be used in 14 V, 24 V and 48 V powered systems
- Instant transmitter shut-down interface (BGE pin)

### 2.2 Low-power management

- Very low current consumption in Standby mode
- Remote wake-up via a wake-up pattern or dedicated FlexRay data frames on the bus lines

### 2.3 Diagnosis and robustness

- Enhanced supply voltage monitoring for  $V_{CC}$  and  $V_{IO}$
- Two error diagnosis modes:
  - ◆ Status register readout via the Serial Peripheral Interface (SPI)
  - ◆ Simple error indication via pin ERRN
- Overtemperature detection
- Short-circuit detection on bus lines
- Power-on flag
- Clamping diagnosis for pins TXEN and BGE
- Bus pins protected against  $\pm 6$  kV ESD pulses according to IEC61000-4-2 and  $\pm 8$  kV according to HBM
- Bus pins protected against transients in automotive environment (according to ISO 7637 class C)
- Bus pins short-circuit proof to battery voltage (14 V, 24 V and 48 V) and ground
- Maximum differential voltage between pins BP or BM and any other pin of  $\pm 60$  V
- Bus lines remain passive when the transceiver is not powered
- No reverse currents from the digital input pins to  $V_{IO}$  or  $V_{CC}$  when the transceiver is not powered

### 2.4 Functional classes according to FlexRay Electrical Physical Layer specification V3.0.1

- Bus driver - increased voltage amplitude transmitter
- Bus driver - bus guardian control interface
- Bus driver - logic level adaptation
- Bus driver - remote wake-up

## 6. Functional description

### 6.1 Power modes

The TJA1083 features three power modes: Normal, Standby and Power-off. Normal and Standby modes can be selected via the STBN input (HIGH for Normal mode) once the transceiver has been powered up. See [Table 3](#) for a detailed description of pin signaling in the three power modes.

Table 3. Pin signaling in the different power modes

Mode	STBN	UV at V <sub>Io</sub>	UV at V <sub>CC</sub>	ERRN		RXD		SDO	Biasing BP, BM	UV-det	Transmitter	Low-power receiver
				LOW	HIGH	LOW	HIGH

Power-off	X	X <sup>[5]</sup>	yes	high-impedance		HIGH			GND <sup>[6]</sup>	disabled		disabled

[1] The wake flag is set if a valid wake-up event is detected while switching to Standby mode.

[2] The wake flag is set if a valid wake-up event is detected.

[3]  $V_{\text{uvd}(V_{\text{CC}})} > V_{\text{CC}} > V_{\text{th}(\text{det})\text{POR}}$ .

[4] Pins ERRN and RXD reflect the state of the wake flag prior to the V<sub>CC</sub> undervoltage event.

[5] The internal signals at pins STBN, BGE and TXD are set LOW; the internal signals at pins TXEN, SCLK and SCSN are set HIGH.

[6] Except when V<sub>CC</sub> = 0; in this case BP and BM are floating.

### 6.1.1 Normal mode

In Normal mode, the transceiver transmits and receives data via the bus lines BP and BM. The transmitter and the normal receiver are enabled, along with the undervoltage detection function. The timing diagram for Normal mode is illustrated in [Figure 3](#).

Fig 3. Timing diagram for Normal mode

Table 4 describes the behavior of the transmitter in Normal mode, when the temperature flag (TEMP HIGH) is not set and with no time-out on pin TXEN. Transmitter behavior is illustrated in Figure 13.

Table 4. Transmitter operation in Normal mode

BGE	TXEN	TXD	Bus state	Transmitter
L	X	X	idle	transmitter is disabled
X	H	X	idle	transmitter is disabled
H	L	H	DATA_1	transmitter is enabled; the bus lines are actively driven; BP is driven HIGH and BM is driven LOW
H	L	L	DATA_0	transmitter is enabled; the bus lines are actively driven; BP is driven LOW and BM is driven HIGH

The transmitter is activated during the first LOW level on pin TXD while pin BGE is HIGH and pin TXEN is LOW.

In Normal mode, the normal receiver output is connected directly to pin RXD (see Table 5). Receiver behavior is illustrated in Figure 14.

Table 5. Behavior of normal receiver in Normal mode

Bus state	RXD
DATA_0	L
DATA_1	H
idle	H

When  $V_{IO}$  and  $V_{CC}$  are within their operating ranges, pin ERRN indicates the status of the error flag. See Section 6.8 for a detailed description of error signaling in Normal mode.

### 6.1.1.1 Bus activity and idle detection

In Normal mode, bus activity and bus idle are detected as follows:

- Bus activity is detected when the absolute differential voltage on the bus lines is higher than  $|V_{i(dif)det(act)}|$  for  $t_{det(act)(bus)}$ :
  - If the differential voltage on the bus lines is lower than  $V_{L(dif)}$  after bus activity has been detected, pin RXD switches LOW.
  - If the differential voltage on the bus lines is higher than  $V_{H(dif)}$  after bus activity has been detected, pin RXD remains HIGH.
- Bus idle is detected when the absolute differential voltage on the bus lines is lower than  $|V_{i(dif)det(act)}|$  for  $t_{det(idle)(bus)}$ . This results in pin RXD being switched HIGH or staying HIGH.

### 6.1.2 Standby mode

Standby mode is a low-power mode featuring very low current consumption. In Standby mode, the transceiver is unable to transmit or receive data since both the transmitter and the normal receiver are switched off. The low-power receiver is activated to monitor the bus for wake-up activity, provided an undervoltage has not been detected on pin  $V_{CC}$ .

The low-power receiver is deactivated if an undervoltage is detected on pin  $V_{CC}$  - with the result that the wake flag is not set if a wake-up pattern or dedicated data frame is received.

Pins ERRN and RXD indicate the status of the wake flag when  $V_{IO}$  and  $V_{CC}$  are within their operating ranges. See [Table 3](#) for a description of pins ERRN and RXD when an undervoltage is detected on pin  $V_{IO}$  or pin  $V_{CC}$ .

The status register cannot be read via the SPI interface if an undervoltage is detected on pin  $V_{IO}$ .

The BGE input has no effect in Standby mode.

### 6.1.3 Power-off mode

The transmitter and the two receivers (normal and low-power) are deactivated in Power-off mode. As a result, the wake flag is not set if a wake-up pattern or dedicated data frame is received. If the voltage at  $V_{CC}$  rises above  $V_{th(rec)POR}$ , the transceiver switches to Standby mode and the digital section is reset. If  $V_{CC}$  subsequently drops below  $V_{th(det)POR}$ , the transceiver reverts to Power-off mode (see [Section 6.2](#)).

The status register cannot be read via the SPI interface in Power-off mode.

### 6.1.4 State transitions

[Figure 4](#) shows the TJA1083 state transition diagram. The timing diagram for the ERRN indication signal during transitions between Normal and Standby modes, when the error flag is set and the wake flag is not set, is illustrated in [Figure 5](#) and described in [Table 6](#).

## 6.2 Power-up and power-down behavior

### 6.2.1 Power-up

The TJA1083 has two supply pins:  $V_{CC}$  (+5 V) and  $V_{IO}$  (for the voltage level adaptation). The ramp up of the different power supplies can vary, depending on the state or value of a number of signals and parameters. The power-up behavior of the TJA1083 is not affected by the sequence in which power is supplied to these pins or by the voltage ramp up.

As an example, [Figure 6](#) shows one possible power supply ramp-up scenario. The digital section of the TJA1083 is supplied by  $V_{CC}$ . The voltage on pin  $V_{CC}$  ramps up before the voltage on pin  $V_{IO}$ . As long as the voltage on  $V_{CC}$  remains below the power-on reset recovery threshold,  $V_{th(rec)POR}$ , the internal state machine is inactive and the transceiver is totally passive, remaining in Power-off mode. As soon as the voltage rises above the  $V_{th(rec)POR}$  threshold, the internal state machine starts running, setting the PWON flag and switching the TJA1083 to Standby mode. This initializes the  $V_{CC}$  and  $V_{IO}$  under-voltage flags to the set state (since both  $V_{CC}$  and  $V_{IO}$  are actually in undervoltage state just after power-on).

Once both  $V_{IO}$  and  $V_{CC}$  have reached their operating ranges, the under-voltage flags are reset. The operating mode is then determined by the level on STBN (the TJA1083 switches to Normal mode if STBN is HIGH and remains in Standby mode if STBN is LOW), provided  $V_{IO}$  and  $V_{CC}$  are above their respective undervoltage recovery levels ( $V_{uvr}(V_{IO})$  and  $V_{uvr}(V_{CC})$ ).

Fig 6. Power-up behavior (example)

6.2.2 Power-down

The behavior of the TJA1083 during power-down is illustrated in [Figure 7](#).

Fig 7. Power-down behavior (example)

### 6.3 Remote wake-up

#### 6.3.1 Bus wake-up via wake-up pattern

A valid remote wake-up event occurs when a wake-up pattern is received. A wake-up pattern consists of at least two consecutive wake-up symbols. A wake-up symbol comprises a DATA\_0 phase lasting longer than  $t_{det(wake)DATA\_0}$  followed by an idle phase lasting longer than  $t_{det(wake)idle}$ , provided both wake-up symbols occur within a time span of  $t_{det(wake)tot}$  (see Figure 8). The transceiver also wakes up if DATA\_1 phases are substituted for the idle phases.

Fig 8. Bus wake-up timing

See Ref. 1 for more details of the wake-up mechanism.

#### 6.3.2 Bus wake-up via dedicated FlexRay data frame

The TJA1083 wake flag is set when a dedicated data frame emulating a valid wake-up pattern, as shown in Figure 9, is received.

The DATA\_0 and DATA\_1 phases of the emulated wake-up symbol are interrupted by the Byte Start Sequence (BSS) preceding each byte in the data frame. With a data rate of 10 Mbit/s, the interruption has a maximum duration of 130 ns and does not prevent the transceiver from recognizing the wake-up pattern in the payload.

For longer interruptions at lower data rates (5 Mbit/s and 2.5 Mbit/s), the wake-up pattern should be used (see Section 6.3.1).

The wake flag is not set if an invalid wake-up pattern is received. See Ref. 1 for more details on invalid wake-up patterns.

The duration of each interruption is 130 ns.

The transition time from DATA\_0 to DATA\_1 and vice versa is about 20 ns.

The TJA1083 wake-up flag is set on receipt of the following frame payload:

```
0xFF, 0xFF, 0xFF, 0xFF, 0xFF, 0x00, 0x00, 0x00, 0x00, 0x00,
0xFF, 0xFF, 0xFF, 0xFF, 0xFF, 0x00, 0x00, 0x00, 0x00, 0x00,
0xFF, 0xFF, 0xFF, 0xFF, 0xFF, 0x00, 0x00, 0x00, 0x00, 0x00,
0xFF, 0xFF, 0xFF, 0xFF, 0xFF
```

**Fig 9. Minimum bus pattern for bus wake-up via dedicated FlexRay data frame**

### 6.4 Bus error detection

The TJA1083 detects the following bus errors during transmission:

- Short-circuit BP to BM at the ECU connector or on the bus
- Short-circuit BP to GND at the ECU connector or on the bus
- Short-circuit BM to GND at the ECU connector or on the bus
- Short-circuit BP to V<sub>CC</sub> at the ECU connector or on the bus
- Short-circuit BM to V<sub>CC</sub> at the ECU connector or on the bus

The bus error flag is not set when a wake-up pattern or a FlexRay Collision Avoidance Symbol (CAS) is being transmitted or received.

### 6.5 Fail silent behavior

Three mechanisms guarantee the 'fail silent' behavior of the TJA1083:

- The TXEN clamped flag is set if pin TXEN goes LOW for longer than  $t_{detCL}(TXEN)$  in Normal mode; the transmitter is disabled.
- The BGE clamped flag is set if pin BGE goes HIGH for longer than  $t_{detCL}(BGE)$  in Normal mode; no action is taken.
- If a loss-of-ground occurs at the transceiver, resulting in the TJA1083 switching to Power-off mode, no current flows out of the digital input pins (TXD, TXEN, BGE, STBN, SCLK, SCSN); see [Table 3](#) for details of the behavior of the bus pins.

### 6.6 TJA1083 flags

The TJA1083 has 11 status/error flags. These are described in [Table 7](#).

Table 7. TJA1083 flags and set/reset conditions

Flag name	Flag type	Flag description	Set condition	Reset condition <sup>[1]</sup>	Consequence of flag set
bus wake	status flag	indicates if a wake-up event has occurred	wake-up event on bus in Standby mode <sup>[2]</sup>	transition to Normal mode	RXD → LOW; ERRN → LOW <sup>[3]</sup>
Normal mode	status flag	indicates if the transceiver is in Normal mode	entering Normal mode	leaving Normal mode	-
transmitter enabled	status flag	indicates the transmitter status	transmitter enabled <sup>[4]</sup>	transmitter disabled	-
BGE clamped	status flag	indicates if pin BGE is clamped	BGE HIGH for longer than $t_{detCL}(BGE)$ <sup>[5]</sup>	BGE LOW <sup>[5]</sup>	-
PWON	status flag	indicates when the digital section is initialized	$V_{CC} > V_{th(rec)POR}$	transition to Normal mode	-
bus error	error flag	indicates if a bus error has been detected	bus error detected <sup>[5]</sup>	no bus error detected or positive edge on TXEN <sup>[5]</sup>	ERRN → LOW <sup>[6]</sup>
TEMP HIGH	error flag	indicates if the max. junction temperature has been reached	$T_{vj} > T_{j(dis)(high)}$ <sup>[5]</sup>	TXEN = HIGH while $T_{vj} < T_{j(dis)(high)}$ <sup>[5]</sup>	ERRN → LOW <sup>[6]</sup> ; transmitter disabled
TXEN clamped	error flag	indicates if pin TXEN is clamped	TXEN LOW for longer than $t_{detCL}(TXEN)$ <sup>[5]</sup>	TXEN = HIGH <sup>[5]</sup>	ERRN → LOW <sup>[6]</sup> ; transmitter disabled
UVV <sub>CC</sub>	error flag	indicates if there is an undervoltage at pin V <sub>CC</sub>	$V_{CC} < V_{uvd}(V_{CC})$ for longer than $t_{det}(uv)(V_{CC})$	$V_{CC} > V_{uvr}(V_{CC})$ for longer than $t_{rec}(uv)(V_{CC})$	ERRN → LOW <sup>[6]</sup> ; entering Standby mode
UVV <sub>IO</sub>	error flag	indicates if there is an undervoltage at pin V <sub>IO</sub>	$V_{IO} < V_{uvd}(V_{IO})$ for longer than $t_{det}(uv)(V_{IO})$	$V_{IO} > V_{uvr}(V_{IO})$ for longer than $t_{rec}(uv)(V_{IO})$	ERRN → LOW <sup>[6]</sup> ; entering Standby mode
SPI error	error flag	indicates if an SPI error has occurred	SPI error detected <sup>[8]</sup>	falling edge on SCSN	ERRN → LOW <sup>[7]</sup> ; SDO goes to a high impedance state

[1] All flags, except for the PWON flag, are reset after a power-on reset.

[2] If an undervoltage has not been detected on pin V<sub>CC</sub>.

[3] If STBN = LOW.

[4] If BGE = HIGH, the Normal mode flag is set, the TEMP HIGH flag is not set and the TXEN clamped flag is not set.

[5] Flag can only be set or reset in Normal mode or on leaving Normal mode.

[6] If STBN = HIGH.

[7] If STBN = HIGH in SPI mode

[8] The SPI error flag is set when:

- more than 16 falling edges occur on pin SCLK while pin SCSN = LOW
- less than 16 falling edges occur on pin SCLK while pin SCSN = LOW.

## 6.7 TJA1083 status register

The TJA1083 contains a 16-bit status register, of which bits S0 to S4 reflect the state of the status flags, bits S5 to S10 reflect the state of the error flags and bit S15 is a parity bit. All flags can be individually read out on pin SDO via a 16-bit SPI interface when the transceiver is configured in SPI mode. The status register bits are described in [Table 8](#).

Table 8. TJA1083 status register

Status bit	Flag name	Set condition	Reset condition
S0	bus wake	bus wake flag set	bus wake flag cleared
S1	Normal mode	Normal mode flag set	Normal mode flag cleared
S2	transmitter enabled	transmitter enabled flag set	transmitter enabled flag cleared
S3	BGE clamped	BGE clamped flag set	BGE clamped flag cleared
S4	PWON	PWON flag set	PWON flag cleared and successful readout <sup>[1]</sup>
S5	bus error	bus error flag set	bus error flag cleared and successful readout <sup>[1]</sup>
S6	TEMP HIGH	TEMP HIGH flag set	TEMP HIGH flag cleared and successful readout <sup>[1]</sup>

S11	reserved	always LOW	
S12	reserved	always HIGH	
S13	reserved	always LOW	
S14	reserved	always HIGH	
S15	parity bit	odd parity of status bits	even parity of status bits

[1] Also cleared during Power-off.

## 6.8 Error signaling

The TJA1083 provides two modes for error indication:

- Simple error indication mode
- SPI mode (default mode)

SPI mode is active on power-up.

To switch to simple error indication mode, SCSN must be held LOW (connected to GND) and SCLK held HIGH (connected to V<sub>IO</sub>) for longer than  $t_{\text{det(L)}(\text{SCLK})}$  (provided a V<sub>IO</sub> undervoltage has not occurred). When the TJA1083 is in simple error indication mode, a rising edge on SCSN initiates a transition to SPI mode (again provided a V<sub>IO</sub> undervoltage has not occurred); see [Figure 10](#).

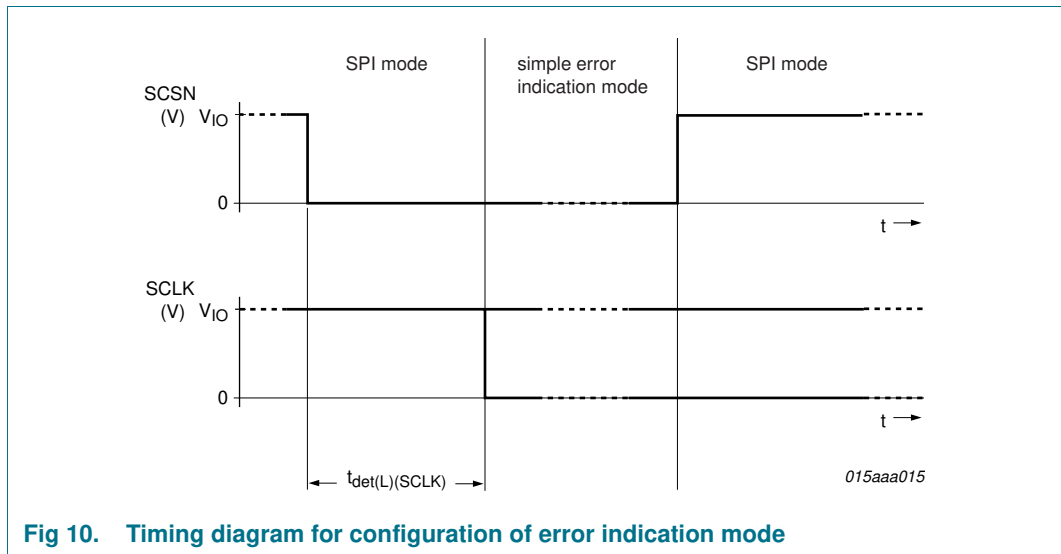

Fig 10. Timing diagram for configuration of error indication mode

If a  $V_{IO}$  undervoltage condition is detected, it is not possible to switch between SPI mode and simple error indication mode.

### 6.8.1 SPI mode

The error flag information in the status register is latched in SPI mode. This means that the status bit is reset once the status register has been completely read (provided the corresponding error flag has been reset). If an error condition is detected in Normal mode, pin ERRN goes LOW (provided one of the error bits, S5 to S10, is set). Pin ERRN goes HIGH again once all the error bits have been reset.

### 6.8.2 Simple error indication mode

If an error condition is detected in Normal mode, pin ERRN goes LOW once the relevant error flag has been set. Pin ERRN stays stable for at least  $t_{ERRNL(min)}$  and goes HIGH again when all error conditions have been cleared and all flags have been reset. Error flags are not latched. It is not possible to read-out the status bits in this mode.

## 6.9 SPI interface

The TJA1083 includes a 16-bit SPI interface to enable a host to read the status register when the transceiver is in SPI mode (see [Section 6.8](#)).

While pin SCSN is HIGH, the SDO output is in a high-impedance state. To begin a status register readout, the host must force pin SCSN LOW. This action causes the SDO pin to output a LOW level by default. The data on pin SDO is then shifted out on the rising edge of the clock signal on pin SCLK.

The status bits shifted out on pin SDO are active HIGH. The status bits are refreshed and pin SDO returned to a high-impedance state once the status register has been read successfully (after exactly 16 clock cycles) and SCSN has been forced HIGH again. Clock signals on SCLK are ignored while SCSN is HIGH. The timing diagram for the SPI readout is illustrated in [Figure 11](#).

The SCLK period ranges from 500 ns to 100  $\mu$ s (10 kbit/s to 2 Mbit/s).

If SCSN remains LOW for longer than 16 clock cycles, it is recognized as an SPI error. When this happens, the SPI error flag is set and pin SDO goes to a high-impedance state until the next falling edge on pin SCSN.

An SPI error is also assumed if fewer than 16 clock cycles are received while SCSN is LOW. If this happens, the SPI error flag is set.

All status bits are refreshed once the status register has been successfully read.

When the transceiver is in simple error indication mode the SDO output is in a high-impedance state and pin SCSN is in pull-down mode. In SPI mode pin SCSN is in pull-up mode.

SPI readout is not possible when the transceiver has detected an undervoltage on  $V_{IO}$ .
