# imall

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from, Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## TSU101, TSU102, TSU104

# Nanopower, rail-to-rail input and output, 5 V CMOS operational amplifiers

Datasheet - production data

## Features

- Submicro ampere current consumption: 580 nA typ per channel at 25 °C at V<sub>CC</sub> = 1.8 V
- Low supply voltage: 1.5 V 5.5 V
- Unity gain stable
- Rail-to-rail input and output
- Gain bandwidth product: 8 kHz typ
- Low input bias current: 5 pA max at 25 °C
- High tolerance to ESD: 2 kV HBM
- Industrial temperature range: -40 °C to 85 °C

#### **Benefits**

- 42 years of typical equivalent lifetime (for TSU101) if supplied by a 220 mAh coin type Lithium battery
- Tolerance to power supply transient drops
- Accurate signal conditioning of high impedance sensors
- Application performances guaranteed over industrial temperature range
- Fast desaturation

## Applications

- Ultra long life battery-powered applications
- Power metering
- UV and photo sensors
- Electrochemical and gas sensors
- Pyroelectric passive infrared (PIR) detection
- Battery current sensing
- Medical instrumentation
- RFID readers

## Description

The TSU101, TSU102, and TSU104 operational amplifiers offer an ultra low-power consumption of 580 nA typical and 750 nA maximum per channel when supplied by 1.8 V. Combined with a supply voltage range of 1.5 V to 5.5 V, these features allow the TSU10x series to be efficiently supplied by a coin type Lithium battery or a regulated voltage in low-power applications.

The 8 kHz gain bandwidth of these devices make them ideal for sensor signal conditioning, battery supplied, and portable applications.

#### Notes:

<sup>(1)</sup>All voltage values, except the differential voltage are with respect to the network ground terminal.

<sup>(2)</sup>The differential voltage is the non-inverting input terminal with respect to the inverting input terminal.

 $^{(3)}((V_{CC+})$  -  $V_{in})$  must not exceed 6 V, (V\_in - V\_{CC-}) must not exceed 6 V.

 $\ensuremath{^{(4)}}\xspace$  The input current must be limited by a resistor in series with the inputs.

 $^{(5)}R_{th}$  are typical values.

<sup>(6)</sup>Short-circuits can cause excessive heating and destructive dissipation.

## 4 Application information

## 4.1 Operating voltages

The TSU101, TSU102, and TSU104 series of amplifiers can operate from 1.5 V to 5.5 V. Their parameters are fully specified at 1.8 V, 3.3 V, and 5 V supply voltages and are very stable in the full V<sub>CC</sub> range. Additionally, main specifications are guaranteed on the industrial temperature range from -40 to 85 °C.

## 4.2 Rail-to-rail input

The TSU101, TSU102, and TSU104 series is built with two complementary PMOS and NMOS input differential pairs. Thus, these devices have a rail-to-rail input, and the input common mode range is extended from ( $V_{CC-}$ ) - 0.1 V to ( $V_{CC+}$ ) + 0.1 V.

The devices have been designed to prevent phase reversal behavior.

## 4.3 Input offset voltage drift over temperature

The maximum input voltage drift over the temperature variation is defined as the offset variation related to the offset value measured at 25 °C. The operational amplifier is one of the main circuits of the signal conditioning chain, and the amplifier input offset is a major contributor to the chain accuracy. The signal chain accuracy at 25 °C can be compensated during production at application level. The maximum input voltage drift over temperature enables the system designer to anticipate the effects of temperature variations.

The maximum input voltage drift over temperature is computed using *Equation 1*.

#### **Equation 1**

$$\frac{\Delta V_{io}}{\Delta T} = \max \left| \frac{V_{io}(T) - V_{io}(25 \,^{\circ}\text{C})}{T - 25 \,^{\circ}\text{C}} \right|$$

with T = -40 °C and 85 °C.

The datasheet maximum value is guaranteed by measurements on a representative sample size ensuring a  $C_{pk}$  (process capability index) greater than 2.

## 4.4 Long term input offset voltage drift

To evaluate product reliability, two types of stress acceleration are used:

- Voltage acceleration, by changing the applied voltage
- Temperature acceleration, by changing the die temperature (below the maximum junction temperature allowed by the technology) with the ambient temperature.

The voltage acceleration has been defined based on JEDEC results, and is defined using *Equation 2*.

#### **Equation 2**

$$A_{FV} = e^{\beta \cdot (V_S - V_U)}$$

Where:

 $A_{FV}$  is the voltage acceleration factor

b is the voltage acceleration constant in 1/V, constant technology parameter ( $\beta = 1$ )

 $V_{\rm S}$  is the stress voltage used for the accelerated test

 $V_U$  is the voltage used for the application

The temperature acceleration is driven by the Arrhenius model, and is defined in *Equation 3*.

#### **Equation 3**

$$A_{FT} = e^{\frac{E_a}{k} \cdot \left(\frac{1}{T_U} - \frac{1}{T_S}\right)}$$

Where:

A<sub>FT</sub> is the temperature acceleration factor

E<sub>a</sub> is the activation energy of the technology based on the failure rate

k is the Boltzmann constant  $(8.6173 \times 10^{-5} \text{ eVk}^{-1})$ 

 $T_U$  is the temperature of the die when  $V_U$  is used (°K)

T<sub>S</sub> is the temperature of the die under temperature stress (°K)

The final acceleration factor,  $A_F$ , is the multiplication of the voltage acceleration factor and the temperature acceleration factor (*Equation 4*).

#### **Equation 4**

$$A_F = A_{FT} \times A_{FV}$$

 $A_F$  is calculated using the temperature and voltage defined in the mission profile of the product. The  $A_F$  value can then be used in *Equation 5* to calculate the number of months of use equivalent to 1000 hours of reliable stress duration.

#### **Equation 5**

Months =  $A_F \times 1000 \text{ h} \times 12 \text{ months} / (24 \text{ h} \times 365.25 \text{ days})$ 

To evaluate the op-amp reliability, a follower stress condition is used where  $V_{CC}$  is defined as a function of the maximum operating voltage and the absolute maximum rating (as recommended by JEDEC rules).

The V<sub>io</sub> drift (in  $\mu$ V) of the product after 1000 h of stress is tracked with parameters at different measurement conditions (see *Equation 6*).

#### Equation 6

 $V_{CC} = maxV_{op}$  with  $V_{icm} = V_{CC}/2$ 

The long term drift parameter ( $\Delta V_{io}$ ), estimating the reliability performance of the product, is obtained using the ratio of the V<sub>io</sub> (input offset voltage value) drift over the square root of the calculated number of months (*Equation 7*).

#### **Equation 7**

$$\Delta V_{io} = \frac{V_{io} drift}{\sqrt{(month s)}}$$

where  $V_{io}\xspace$  drift is the measured drift value in the specified test conditions after 1000 h stress duration.

### 4.5 Schematic optimization aiming for nanopower

To benefit from the full performance of the TSU10 series, the impedances must be maximized so that current consumption is not lost where it is not required.

For example, an aluminum electrolytic capacitance can have significantly high leakage. This leakage may be greater than the current consumption of the op-amp. For this reason, ceramic type capacitors are preferred.

For the same reason, big resistor values should be used in the feedback loop. However, there are three main limitations to be considered when choosing a resistor.

- 1. When the TSU10x series is used with a sensor: the resistance connected between the sensor and the input must remain much higher than the impedance of the sensor itself.
- 2. Noise generated: a 100 k $\Omega$  resistor generates 40 nV/ $\sqrt{Hz}$ , a bigger resistor value generates even more noise.
- 3. Leakage on the PCB: leakage can be generated by moisture. This can be improved by using a specific coating process on the PCB.

## 4.6 PCB layout considerations

For correct operation, it is advised to add 10 nF decoupling capacitors as close as possible to the power supply pins.

Minimizing the leakage from sensitive high impedance nodes on the inputs of the TSU10x series can be performed with a guarding technique. The technique consists of surrounding high impedance tracks by a low impedance track (the ring). The ring is at the same electrical potential as the high impedance node.

Therefore, even if some parasitic impedance exists between the tracks, no leakage current can flow through them as they are at the same potential (see *Figure 38: "Guarding on the PCB"*).

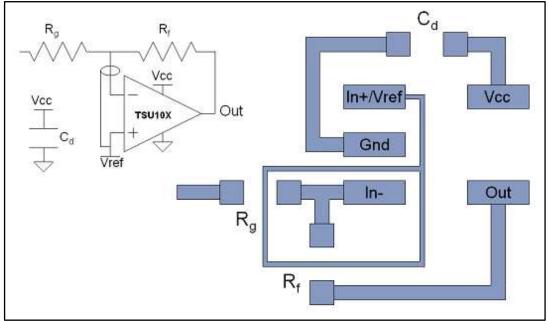

Figure 38: Guarding on the PCB

## 4.7 Using the TSU10x series with sensors

The TSU10x series has MOS inputs, thus input bias currents can be guaranteed down to 5 pA maximum at ambient temperature. This is an important parameter when the operational amplifier is used in combination with high impedance sensors.

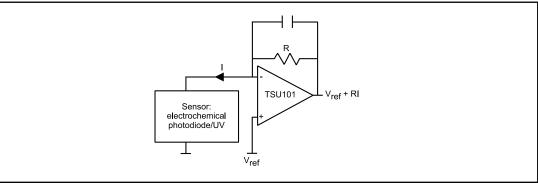

The TSU101, TSU102, and TSU104 series is perfectly suited for trans-impedance configuration as shown in *Figure 39: "Trans-impedance amplifier schematic"*. This configuration allows a current to be converted into a voltage value with a gain set by the user. It is an ideal choice for portable electrochemical gas sensing or photo/UV sensing applications. The TSU10x series, using trans-impedance configuration, is able to provide a voltage value based on the physical parameter sensed by the sensor.

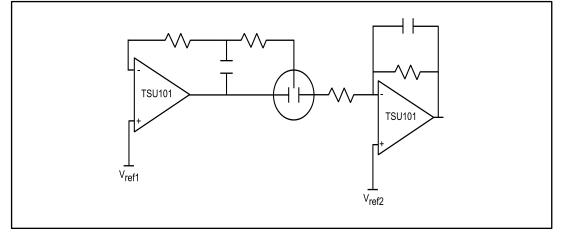

#### **Electrochemical gas sensors**

The output current of electrochemical gas sensors is generally in the range of tens of nA to hundreds of  $\mu$ A. As the input bias current of the TSU101, TSU102, and TSU104 is very low (see *Figure 9, Figure 10*, and *Figure 11*) compared to these current values, the TSU10x series is well adapted for use with the electrochemical sensors of two or three electrodes. *Figure 40: "Potentiostat schematic using the TSU101 (or TSU102)"* shows a potentiostat (electronic hardware required to control a three-electrode cell) schematic using the TSU101, TSU102, and TSU104. In such a configuration, the devices minimize leakage in the reference electrode compared to the current being measured on the working electrode.

#### Figure 40: Potentiostat schematic using the TSU101 (or TSU102)

## 4.8 Fast desaturation

When the TSU101, TSU102, and TSU104 operational amplifiers go into saturation mode, they take a short period of time to recover, typically thirty microseconds. When recovering after saturation, the TSU10x series does not exhibit any voltage peaks that could generate issues (such as false alarms) in the application (see *Figure 17*). This is because the internal gain of the amplifier decreases smoothly when the output signal gets close to the  $V_{CC+}$  or  $V_{CC-}$  supply rails (see *Figure 15* and *Figure 16*).

Thus, to maintain signal integrity, the user should take care that the output signal stays at 100 mV from the supply rails.

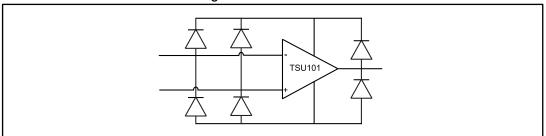

With a trans-impedance schematic, a voltage reference can be used to keep the signal away from the supply rails.

## 4.9 Using the TSU10x series in comparator mode

The TSU10x series can be used as a comparator. In this case, the output stage of the device always operates in saturation mode. In addition, *Figure 4* shows the current consumption is not bigger and even decreases smoothly close to the rails. The TSU101, TSU102, and TSU104 are obviously operational amplifiers and are therefore optimized to be used in linear mode. We recommend to use the TS88 series of nanopower comparators if the primary function is to perform a signal comparison only.

## 4.10 ESD structure of TSU10x series

The TSU101, TSU102, and TSU104 are protected against electrostatic discharge (ESD) with dedicated diodes (see *Figure 41: "ESD structure"*). These diodes must be considered at application level especially when signals applied on the input pins go beyond the power supply rails ( $V_{CC+}$  or  $V_{CC-}$ ).

Current through the diodes must be limited to a maximum of 10 mA as stated in *Table 1:* "*Absolute maximum ratings (AMR)*". A serial resistor or a Schottky diode can be used on the inputs to improve protection but the 10 mA limit of input current must be strictly observed.

## 5 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK<sup>®</sup> packages, depending on their level of environmental compliance. ECOPACK<sup>®</sup> specifications, grade definitions and product status are available at: *www.st.com*. ECOPACK<sup>®</sup> is an ST trademark.
